ABSTRACT

An analysis was conducted to estimate the likelihood of underclassifying ocular corrosives or severe irritants as nonsevere irritants or overclassifying ocular nonsevere irritants and nonirritants as ocular corrosives or severe irritants. The analysis used the current sequential three animal *in vivo* rabbit eye test method and the United Nations (UN) Globally Harmonized System (GHS) of Classification and Labeling of Chemicals. The distribution of individual rabbit responses within each hazard classification was used to estimate the likelihood of under- and over-classification likelihoods for a sequential testing strategy (using from one to three rabbits). Based on assumptions about the variability in rabbit responses among substances within each hazard classification, the estimated underclassification likelihoods, based on 723 rabbits tested in 181 studies, for corrosives/severe irritants (GHS Category 1) ranged from 4.30% to 13.24%. Analyses based on the physical form of the test substance indicated that underclassification likelihoods for solids were lower than for liquids (2.89%-8.31% vs. 5.36%-15.79%, respectively), although these differences are not statistically significant. Estimated underclassification likelihoods were higher when a corrosive/severe irritant classification was based solely on persistent lesions present at observation day 21. By chemical class, carboxylic acids had the highest underclassification likelihood (16.64%). Overclassification likelihoods of nonsevere and nonirritant substances as Category 1 substances, based on 2481 rabbits tested in 596 studies, were estimated to be 6.67% to 7.70% for Category 2A substances, 0.82% to 1.28% for Category 2B substances, and 0.00% for nonirritants. One limitation of this analysis is that it requires an *a priori* assignment of each chemical to a specific irritation category. Using the approach of Springer et al. (1993), the likelihood that an ocular corrosive or severe irritant will be underclassified can be estimated without an *a priori* assignment of each chemical to a specific hazard classification. Using a modified version of the Spring et al. approach, the overall estimated underclassification rate for all irritants was 13.40%, while the estimated overclassification rate for all nonirritants is 2.65%. These rates agree closely with the estimates based on using the previous approach.

46 **1.0 INTRODUCTION**

47

48 **1.1 Background**

49 The Interagency Coordinating Committee on the Validation of Alternative Methods (ICCVAM)
50 is currently evaluating the validation status of four *in vitro* test methods proposed for identifying
51 ocular corrosives and severe ocular irritants. In support of this evaluation, the National
52 Toxicology Program Interagency Center for the Evaluation of Alternative Toxicological
53 Methods (NICEATM) solicited and searched for ocular data from *in vivo* rabbit eye tests and
54 clinical studies that could be used to assess the accuracy of the *in vitro* methods. While it would
55 also be desirable to have sufficient data to assess the reliability of the *in vivo* rabbit eye test and
56 its accuracy for identifying substances that cause ocular corrosion and severe ocular irritation in
57 humans, no data were found to allow such assessments. However, NICEATM was able to
58 analyze available animal data to estimate the likelihood that ocular corrosives or severe irritants
59 might be underclassified and nonsevere irritants or nonirritants overclassified using current
60 testing guidelines due to the variation in individual animal responses. The analysis is based on
61 the ocular irritancy classification system used in the United Nations (UN) Globally Harmonized
62 System (GHS) of Classification and Labeling of Chemicals (UN 2003)¹.

63

64 **1.2 The GHS Classification System (UN 2003)**

65 For the purpose of international harmonization of the classification of ocular irritants, the GHS
66 classification system (UN 2003) includes two categories, one for irreversible effects on the
67 eye/serious damage to the eye (Category 1), and one for reversible effects on the eye (Category
68 2). The GHS categories are based on severity of the lesions and/or the duration of persistence.
69 Reversible effects are further divided, based on the duration of persistence of ocular lesions as
70 Category 2A (“irritating to eyes”) (reverses within 21 days) and Category 2B (“mildly irritating
71 to eyes”) (reverses within seven days).

72

¹Because the GHS classification system (UN 2003) has been internationally harmonized through the UN, and will be implemented globally in the near future, assessment of the *in vivo* rabbit eye test for identifying corrosives and severe irritants, as defined by this classification system, is the focus of this evaluation.

72 **1.3 Accuracy of the Current Test for Identifying Potential Ocular Corrosives and**
73 **Severe Irritants**

74 It would be desirable to determine the accuracy of the current *in vivo* rabbit eye test for
75 identifying substances capable of producing ocular corrosion or severe irritation in humans. A
76 review of the literature indicates that there are few studies in which rabbit and human responses
77 have been carefully compared under controlled conditions to assess the accuracy of the *in vivo*
78 rabbit eye test method. Therefore, most studies conducted a retrospective evaluation and
79 comparison of responses between humans and rabbits. A review indicates that a number of
80 studies show that responses to mild to moderate irritants were generally similar between rabbits
81 and humans (Lewin and Guillory 1913; Suker 1913; Leopold 1945; Carpenter and Smyth 1946;
82 McLaughlin 1946; Nakano 1958; Barkman et al. 1969; Grant 1974; for summaries of the above
83 studies see McDonald et al. 1987). For a severe irritant, Grant (1974) and Butscher (1953)
84 showed that accidental exposure to pure thioglycolic acid produced similar responses in humans
85 and rabbits.

86

87 In comparison to these studies, there have been studies where the responses to ocular irritants are
88 different between human and rabbits. In some of the reviewed studies, the test substances
89 produced more severe responses in humans than in rabbits (Lewin and Guillory 1913; Gartner
90 1944; Estable 1948; Marsh and Maurice 1971; Grant 1974). For example, Marsh and Maurice
91 (1971) evaluated the effects of a 1% concentration of nonionic detergents in humans. The most
92 severe symptoms were associated with 1% Brij 58, which produced blurred vision and halos with
93 corneal epithelial bedewing, with most effects disappearing with 24 hours. Comparatively,
94 Grant (1974) showed that these substances were generally nondamaging to the rabbit eye when
95 tested at high concentrations. Additional examples of disparate effects between humans and
96 rabbits are summarized in McDonald et al. (1987). Studies with some soaps and surfactants and
97 liquid detergents indicated that more severe responses were produced in rabbits than in humans
98 (Calabrese 1983). Differences in exposures, anatomical and physiological differences, and
99 differences in pain thresholds, combined with differences in mechanism of action of test
100 substances are proposed to play some role in the lack of concordant responses between humans
101 and rabbits.

102

103 Accidental human exposure injury data involving severe or irreversible eye injuries also could be
104 used to determine if substances or products causing these human injuries had not been identified
105 in animal studies. Several U.S. Federal agencies (Occupational Health and Safety
106 Administration [OSHA], Consumer Product Safety Commission [CPSC], and the National
107 Institute for Occupational Safety and Health [NIOSH]) were contacted for accidental human
108 exposure data. NIOSH estimated that there were approximately 39,200 chemical-related eye
109 injuries in 1998, based on emergency department reports for work related eye-injuries (NIOSH
110 2004). Approximately 10,000 of these cases were attributed to an unidentified/unspecified
111 chemical and additional cases (<2500 each) were reported for injuries related to specific
112 chemicals or chemical/product classes. However, specific information on which products were
113 involved are not available and details of the types and severity of ocular injuries sustained were
114 not described. Without more detail about the specific nature of the substances and exposure
115 conditions, these accidental human exposure injury data are not useful for evaluating the
116 accuracy of the *in vivo* rabbit eye test for predicting human severe ocular hazard.

117

118 **1.4 Evaluation of the Reproducibility of the Current Rabbit Eye Test Method for**
119 **Ocular Corrosives and Severe Irritants**

120 Evaluating test method reproducibility requires the availability of data from repeat tests
121 conducted on the same substances within and across multiple laboratories. Substances tested
122 should represent the range of possible test outcomes as well as the range of physicochemical
123 properties of the various substances for which the test method is proposed for use.

124

125 For *in vivo* rabbit eye test data to be useful for a direct evaluation of test method reproducibility,
126 data for substances tested multiple times within and across laboratories were needed.
127 Furthermore, to be useful for this analysis,

- 128 • the study had to have been conducted according to the *in vivo* rabbit eye test method
129 protocol described in Draize et al. (1944), by U.S. Federal agencies (e.g., FHS 1964,
130 EPA 1998), or the Organisation for Economic Co-operation and Development (OECD)
131 Test Guideline (TG) 405 (OECD 2002), and
132 • the data provided had to be sufficient for classifying the ocular irritancy of the test
133 substance according to the GHS classification system (UN 2003) (i.e., individual rabbit

134 data was needed at 1, 2, and 3 days post-treatment, as well as to 21 days post-treatment
135 unless the study was terminated early due to severe effects and the rationale for
136 terminating the study was identified).

137

138 In an attempt to obtain such data, NICEATM searched the published literature and published two
139 *Federal Register (FR)* Notices (March 24, 2004; Volume 69, Number 57; Pages 13859-13861
140 and February 28, 2005; Volume 70, Number 38, Pages 9661-9661) requesting high quality *in*
141 *vivo* data from standardized ocular irritancy test methods using rabbits (e.g., EPA 1998; UN
142 2003). In addition, a request for relevant data as well as a copy of the *FR* notice was mailed to
143 officers of 80 national and international organizations (e.g., professional organizations) with
144 interest in this area. Data were sought from studies conducted to comply with Federal or other
145 national/international testing requirements, but are not publicly accessible because the data were
146 submitted to regulatory authorities, but cannot be released to the public due to their proprietary
147 nature.

148

149 Based on the available published and submitted data, the numbers of substances tested multiple
150 times are too few to conduct a direct evaluation of test method intra- or inter-laboratory
151 reproducibility.

152

152 **2.0 MATERIALS AND METHODS**

153

154 **2.1 Database Development**

155 Data compiled for these analyses are from corrosivity and irritation studies conducted using the
 156 *in vivo* rabbit eye test method described by Draize et al. (1994), U.S. Federal agencies (e.g.,
 157 FHSA 1964, EPA 1998) or the OECD TG 405 (OECD 2002). Data sources and the number of
 158 studies considered appropriate for this analysis are provided in **Table 1**.

159

160 **Table 1. Number of Ocular Toxicity Studies from Various Data Sources**

Data Source	Number of Acceptable Corrosives or Severe Irritant Studies	Number of Acceptable Nonsevere Irritant or Nonirritant Studies	GLP-Compliance

161 Abbreviations: CTFA = Cosmetics, Toiletry, and Fragrance Association; ECETOC = European Centre for
 162 Ecotoxicology and Toxicology of Chemicals; EPA = U.S. Environmental Protection Agency; FDA = U.S. Food and
 163 Drug Administration; GLP = Good Laboratory Practice; ISOPA = European Diisocyanate and Polyol Producers
 164 Association; NIHS = Japanese National Institute of Health Sciences; TSCA = Toxic Substances Control Act;
 165 ZEBET = German Center for Documentation and Evaluation of Alternative Methods to Animal Experimentation.

166

167 Not all studies received were considered appropriate for this analysis. Specifically, studies were
 168 excluded that did not follow the standard Draize test protocol and/or did not provide the
 169 individual rabbit data needed to classify the ocular irritancy of a test substance according to the
 170 GHS classification system (UN 2003). Examples of reasons for excluding studies include:

- 171 • The amount administered to the eye of a rabbit was not the standard 0.1 mL or 100 mg,
172 unless a smaller amount was used and, based on the response obtained, the substance
173 could be classified as a GHS ocular corrosive or severe irritant. This criterion was based
174 on the expectation that a substance classified as a nonsevere irritant or nonirritant using a
175 smaller than standard volume might be classified as a severe irritant if the standard
176 volume had been used. In contrast, a substance classified as a corrosive or severe irritant
177 would not be expected to result in a nonsevere or nonirritant classification when tested at
178 the standard volume.
- 179 • The study was terminated prior to day 21 and a positive but noncorrosive response was
180 present in one or more rabbits such that reversibility could not be assessed, unless the
181 study was terminated early for animal welfare reasons and the reason for the early
182 termination was provided in the study documentation.

183

184 Data compiled for this analysis included test substance name or unique identifier; Chemical
185 Abstracts Service Registry Number (CASRN), if available; source of data; chemical class(es);
186 number of rabbits tested; amount of substance administered to the eye of each rabbit; and the
187 ocular response of each rabbit at each time point evaluated. Several of the substances tested
188 were proprietary products, which were identified by a unique identifier and whose formulation
189 and chemical composition were not provided. A summary dataset used for this analysis is
190 provided in **Appendix A**.

191

192 **2.2 Adequacy of *In Vivo* Rabbit Eye Test Data**

193 Ideally, all of the *in vivo* rabbit eye tests should have been conducted in compliance with Good
194 Laboratory Practice (GLP) guidelines. These guidelines are nationally and internationally
195 recognized rules designed to produce high-quality laboratory records (OECD 1998; EPA 2003a,
196 2003b; FDA 2003). To the extent known, compliance with GLP guidelines in the conduct of the
197 study is provided in **Table 1**.

198

199 **2.3 Substance Classification Based on the GHS Classification System (UN 2003)**

200 Prior to evaluating the estimated underclassification and overclassification likelihood of the
201 sequential three animal *in vivo* rabbit eye test method protocol for identifying a substance

202 capable of inducing a corrosive or severe response, individual rabbit responses were classified
 203 according to the GHS classification system (UN 2003). As described in **Section 1.3**, this
 204 classification system delineates substances into three categories: Category 1, Category 2, or
 205 Nonirritant. Category 2 substances can be further divided as Category 2A or 2B, depending on
 206 the time required for reversal of any adverse effects (**Table 2**).
 207

208 For the purpose of this evaluation, Category 1 substances were sub-classified into whether the
 209 classification was based on a single rabbit response (i.e., one of three rabbits with a corneal
 210 opacity score of 4 at any time or a positive response that is not expected to reverse or that does
 211 not fully reverse within 21 days [NICEATM Cat 1A]), or based on at least two of three rabbits
 212 having a mean corneal opacity score ≥ 3 and/or an iritis score > 1.5 (scores for each rabbit are
 213 averaged across observations at days 1, 2, and 3 post-treatment; NICEATM Cat 2A).
 214

215 Based on this classification system, each rabbit tested in the database was assigned one of these
 216 irritancy categories, as described in **Table 2**.
 217

218 **Table 2. Criteria Used for Classification of Rabbits According to the GHS**
 219 **Classification System (UN 2003)**

Rabbit Category	Criteria for Classification
Category 1A (Cat 1A)	- Corneal opacity score of 4 at any time - Rabbit with effects not expected to reverse or that do not fully reverse within 21 days
Category 1B (Cat 1B)	- Rabbit with mean corneal opacity score ≥ 3 and/or iritis score > 1.5 (rabbit values are averaged across observation days 1, 2, and 3)
Category 2A (Cat 2A)	Rabbit with mean scores (rabbit values are averaged across observation days 1, 2, and 3) for one of more of the following: Iritis ≥ 1 Corneal opacity ≥ 1 Redness ≥ 2 Chemosis ≥ 2 and the effects fully reverse within 21 days
Category 2B (Cat 2B)	When the effects listed for Category 2A fully reverse within 7 days
Nonirritant	Rabbit mean scores fall below threshold values for Category 1, 2A, and 2B

220

221 Each substance was then classified based upon the number of rabbits within each category and
222 the following classification rules. Since the current classification system was applied
223 retrospectively to some studies where more than three rabbits were tested, the decision criteria
224 for substance classification were expanded to allow for classification of these substances. When
225 more than three rabbits were tested, the proportionality needed to classify a substance was
226 maintained (e.g., 1 of 3 or 2 of 6 positive rabbits were required for classification for most
227 categories). However, in some cases, additional classification rules were necessary to include
228 the available data. These additional rules are distinguished by italicized text.

229

230 *GHS Category 1*

- 231 1. At least 1 of 3 rabbits or 2 of 6 rabbits classified as Cat 1A.
- 232 2. *One of 6 rabbits classified as Cat 1A and another rabbit classified as Cat 1B.*
- 233 3. At least 2 of 3 rabbits or 4 of 6 rabbits classified as Cat 1B.

234

235 If none of the above options were fulfilled, then the following classifications were applied in
236 sequential order:

237

238 *GHS Category 2A*

- 239 1. At least 2 of 3 rabbits or 4 of 6 rabbits classified as Cat 2A.
- 240 2. *One of 3 (2 of 6) rabbits classified as Cat 2A and 1 of 3 (2 of 6) rabbits classified as Cat*
241 *2B.*

242

243 *GHS Category 2B*

- 244 1. At least 2 of 3 rabbits or 4 of 6 rabbits classified as Cat 2B.

245

246 *GHS Nonirritant*

- 247 1. At least 2 of 3 rabbits or 4 of 6 rabbits classified as nonirritant.

248

249 **2.4 Calculations Performed**

250 The estimated under- and over-classification likelihoods were calculated for each hazard
251 classification based on the decision rules and the observed distribution of rabbit responses among

252 all rabbit responses for each subcategory evaluated. Rabbit responses were denoted by 1A, 1B,
253 2A, 2B, and N (for a Cat 1A, Cat 1B, Cat 2A, Cat 2B, or nonirritant response, respectively).
254 Likewise, the probability that a rabbit would produce each of these responses is denoted by p1A,
255 p1B, p2A, p2B, and pN. The specific test outcomes for a sequential test protocol (up to three
256 rabbits) are as follows:

257

258 *GHS Category 2A*

259 The following outcomes for a sequential test protocol (up to three rabbits) could lead to a test
260 substance being classified as GHS Category 2A:

- 261 1. 2A-2A (testing stopped). This outcome sequence has a probability of $(p2A)x(p2A)$.
- 262 2. 2A-(1B, 2B, or N)-2A, or (1B, 2B, or N)-2A-2A. This outcome sequence has a
263 probability of $2x(p2A)x(p2A)x(p1B+p2B+pN)$.
- 264 3. 2A-2B-N (this outcome can occur in six different orders). This outcome sequence has a
265 total probability of $6x(p2A)x(p2B)x(pN)$.
- 266 4. 2A-2B-Cat1B (this outcome can occur in six different orders). This outcome sequence
267 has a total probability of $6x(p2A)x(p2B)x(p1B)$.

268

269 Summing these four probabilities gives the estimated likelihood for GHS Category 1 substances
270 being underclassified as GHS Category 2A substances and the estimated likelihood for GHS
271 Category 2B or nonirritant substances being overclassified as GHS Category 2A substances. The
272 calculated likelihood also would represent the likelihood of correct classification of GHS
273 Category 2A substances.

274

275 *GHS Category 2B*

276 The following outcomes could lead to a GHS Category 2B classification for a test substance:

- 277 1. 2B-2B (testing stopped). This outcome sequence has a probability of $(p2B)x(p2B)$.
- 278 2. 2B-(2A or 1B or N)-2B (this outcome can occur in two different orders). This outcome
279 sequence has a total probability of $2x(p2B)x(p2B)x(p2A+p1B+pN)$.

280

281 Summing these two probabilities gives the estimated likelihood for GHS Category 1 or 2A
282 substances being underclassified as GHS Category 2B substances and the estimated likelihood

283 for nonirritant substances being over classified as GHS Category 2B substances. The calculated
284 likelihood also would represent the likelihood of correct classification of GHS Category 2B
285 substances.

286

287 *GHS Nonirritant Category*

288 The following outcomes could lead to a nonirritant classification:

- 289 1. N-N (testing stopped). This outcome sequence has a probability of $(pN) \times (pN)$.
- 290 2. N-(1B or 2A or 2B)-N (this outcome can occur in two different orders). This outcome
291 sequence has a total probability of $2 \times (pN) \times (pN) \times (p1B + p2A + p2B)$.

292

293 Summing these two probabilities gives the estimated likelihood for GHS Category 1, 2A, or 2B
294 substances being underclassified as GHS nonirritants. The calculated likelihood also would
295 represent the likelihood of correct classification of nonirritant substances.

296

297 *Variable Responder Category*

298 Using this testing strategy, two different outcomes could lead to the inability to assign an
299 appropriate GHS classification. In these cases, based on the classification rules described in
300 **Section 2.3**, a majority of the rabbits tested are not classified in the same manner. These
301 outcomes were designated as “variable responders”. This classification could occur based on the
302 following rabbit outcomes:

- 303 1. Cat1B-N-2A (this outcome can occur in six different orders). This outcome sequence has
304 a total probability of $6 \times (p1B) \times (pN) \times (p2A)$.
- 305 2. Cat1B-N-2B (this outcome can occur in six different orders). This outcome sequence has
306 a total probability of $6 \times (p1B) \times (pN) \times (p2B)$.

307

308 The probabilities p1A, p1B, p2A, p2B, and pN were estimated from the observed distribution of
309 rabbit responses among all rabbit responses for each subcategory evaluated. Summing these two
310 probabilities gives the estimated likelihood for GHS Category 1, 2A, or 2B substances and
311 nonirritant substances being misclassified as variable responders.

312

312

313 *GHS Category 1*

314 To estimate the overclassification likelihood for GHS Category 2A or 2B substances or
315 nonirritant substances, the likelihood of misclassification (likelihood of underclassification and
316 classification as a variable responder) and correct classification are totaled and subtracted from
317 one.

318

319 Due to the nature of the database (i.e., very few substances were tested multiple times within or
320 across laboratories, the number of rabbits tested ranged from one to six), several different
321 calculations were conducted to develop a range of estimated likelihoods for underclassifying a
322 corrosive or severe irritant as a nonsevere irritant or nonirritant and overclassifying a nonsevere
323 irritant or nonirritant as a corrosive or severe irritant.

324

325 **2.4.1 Calculation 1: Homogeneity of Response for Substances**

326 For this calculation, it was assumed that rabbits have the same (homogeneous) pattern of
327 response for all substances within a given classification category. The advantage of this
328 assumption is that only a single calculation is required to determine the likelihood for
329 underclassifying a corrosive or severe irritant as a nonsevere irritant or nonirritant or
330 overclassifying a nonsevere irritant or nonirritant as a corrosive or severe irritant. However,
331 since the normal variability in response among animals for different test substances is eliminated,
332 the calculation likely will underestimate the overall likelihood.

333

334 **2.4.2 Calculation 2: Heterogeneity of Response for Substances**

335 For this calculation, it is assumed that rabbits have a different (heterogeneous) pattern of
336 response for each study in the database. For this case, the probability of misclassifying a
337 substance is calculated for each study. The individual probabilities are then pooled to determine
338 the overall likelihood. One limitation of this approach is that the distribution of observed rabbit
339 responses for each substance is based on a small number of rabbits (six or less). However, this
340 approach takes into account variability of response among substances. As a result, this method
341 leads to a higher estimated likelihood than Calculation 1.

342

343 2.4.3 Calculation 3: Homogeneity of Response for Three Subgroups of GHS Category 1
344 Substances

345 This calculation was developed as an additional estimate of the underclassification likelihood of
346 Category 1 substances. This calculation was based upon the observation that there were three
347 subgroups of GHS Category 1 eye irritants that showed, internally, a relatively homogeneous
348 response. These three groups are:

- 349 • *Strong responders.* These are GHS Category 1 substances that always produce either a
350 Cat 1A or 1B response in all tested rabbits. In essence, these substances have an
351 estimated underclassification likelihood of zero.
- 352 • *Moderate responders.* These are GHS Category 1 substances that produced a Cat 1
353 response in at least 50% but not 100% of the rabbits tested.
- 354 • *Weak responders.* These are GHS Category 1 substances that produced a nonsevere (i.e.,
355 Cat 2A, 2B) or nonirritant response in more than half of the rabbits tested.

356
357 Using this approach, the estimated underclassification likelihoods are based on the pooled results
358 from three subgroups rather than being based on a single computation (Calculation 1) or the
359 pooled results across studies (Calculation 2). This approach takes into account the presence of
360 subgroups of GHS Category 1 substances differing in the proportion of affected rabbits.

361
362 **2.5 Data Sampling**

363 To conduct these analyses using the calculation methods described above, sampling from data
364 based on sequential testing and stopping rules were used:

365
366 *First Rabbit Sampled from Database*

- 367 • If a rabbit is classified as Cat 1A, then stop test and the substance tested is classified as
368 GHS Category 1.
- 369 • If not, record rabbit classification (e.g., Cat 2B) and then test second rabbit.

370
371 *Second Rabbit Sampled from Database*

- 372 • If second rabbit is classified as Cat 1A, then stop test and the substance tested is
373 classified as GHS Category 1.

- 374 • If second rabbit has the same classification as the first rabbit, (e.g., Cat 2B) then stop test
375 and the substance tested is classified according to the rabbit classifications.
376 • If rabbit responses are different, record rabbit classification and then test third rabbit.

377

378 *Third Rabbit Sampled from Database*

- 379 • If third rabbit is classified as Cat 1A, then stop test and the substance tested is classified
380 as GHS Category 1.
381 • Otherwise, record classification of third rabbit.
382 • If two of the three rabbits have the same classification, then that classification is used for
383 the substance tested.
384 • If one rabbit is classified as Cat 2B and at least one rabbit is classified as Cat 2A, then the
385 substance tested is classified as GHS Category 2A.
386 • If all rabbits have different classification (e.g., Cat 1B, Cat 2A, and nonirritant), then the
387 substance tested is identified as a “variable responder.”

405

405 **3.0 Underclassification Likelihood Calculations for GHS Category 1 Substances**

406

407 Underclassification likelihoods were estimated for the total database and for certain subsets of
408 the total database (e.g., solids versus liquids/gels, selected chemical classes, four different GHS
409 criteria used to identify a severe irritant or corrosive).

410

411 **3.1 Calculation 1: Homogeneity of Response for GHS Category 1 Substances**

412 The distribution of rabbit responses for GHS Category 1 irritants is given in **Table A** in
413 **Appendix B**. The calculations are illustrated using the values from the database (**Table A** in
414 **Appendix B**) and the assignment probabilities described previously (see **Section 2.4**).

415

416 *GHS Category 2A*

417 The likelihood of a GHS Category 1 substance being underclassified as a GHS Category 2A
418 substance is the sum of the following four probabilities, which is 0.0300:

- 419 1. $(96/723) \times (96/723) = 0.0176$
420 2. $2 \times (96/723) \times (128/723) \times (96/723) = 0.00624$
421 3. $6 \times (96/723) \times (58/723) \times (20/723) = 0.00177$
422 4. $6 \times (96/723) \times (58/723) \times (50/723) = 0.00442$

423

424 *GHS Category 2B*

425 The estimated underclassification likelihood of a GHS Category 1 substance being
426 underclassified as a Category 2B substance is the sum of the following two probabilities, which
427 is 0.0094:

- 428 1. $(58/723) \times (58/723) = 0.00644$
429 2. $2 \times (58/723) \times (58/723) \times (166/723) = 0.00296$

430

431 *GHS Nonirritant*

432 The estimated underclassification likelihood of a GHS Category 1 substance being
433 underclassified as a GHS nonirritant is the sum of the following two probabilities, which is
434 0.0012:

- 435 1. $(20/723) \times (20/723) = 0.00077$

436 2. $2 \times (20/723) \times (204/723) \times (20/723) = 0.00043$

437

438 *Variable Responder*

439 Finally, the likelihood of a GHS Category 1 substance being underclassified as a “variable
440 responder” is the sum of the following two probabilities, which is 0.0024:

441 1. $6 \times (50/723) \times (20/723) \times (96/723) = 0.00152$

442 2. $6 \times (50/723) \times (20/723) \times (58/723) = 0.00092$

443

444 Adding these summed probabilities for these four categories yields 0.0430 (see **Table 3**) as the
445 overall estimated underclassification likelihood for GHS Category 1 substances.

446

447 **Table 3. Estimated Underclassification Likelihoods for GHS Category 1 Substances
448 Using Calculation 1 (Assumes Homogeneity of Response)**

Category	Total Database
GHS Category 2A	0.0300
GHS Category 2B	0.0094
GHS Nonirritants	0.0012
Variable Responders	0.0024
Total	0.0430 (4.30%)

449 See **Table A** in **Appendix B** for the distribution of rabbit responses used to
450 assess underclassification likelihood for GHS Category 1 substances
451 (Calculation 1).

452

453 **3.2 Calculation 2: Heterogeneity of Response for GHS Category 1 Substances**

454 The pattern of rabbit responses (i.e., Cat 1A, Cat 1B, Cat 2A, Cat 2B, nonirritant) observed for
455 the individual GHS Category 1 studies in the total database is provided in **Table B** in **Appendix**
456 **B**. Based on these probabilities, the estimated underclassification likelihood can be calculated
457 for the heterogeneity assumption. Similar to the Calculation 1 method, the likelihood of a
458 substance being underclassified is calculated for each outcome listed in **Table B** in **Appendix B**.
459 For each irritancy class (e.g., GHS Category 2A), the classification probabilities are then
460 averaged across substances to obtain the overall estimated underclassification likelihood (**Table**
461 **4**).
462

462 **Table 4. Estimated Underclassification Likelihoods for GHS Category 1 Substances**
 463 **Using Calculation 2 (Assumes Heterogeneity of Response)**

Category	Total Database
GHS Category 2A	0.0751
GHS Category 2B	0.0429
GHS Nonirritants	0.0144
Variable Responders	0.0000
Total	0.1324 (13.24%)

464 See **Table B** in **Appendix B** for the distribution of rabbit responses used to assess
 465 underclassification likelihood for GHS Category 1 substances (Calculation 2).

466

467 **3.3 Calculation 3: Homogeneity of Response for Three Subgroups of GHS Category 1**
 468 **Substances Identified by Distribution of Rabbit Responses within Studies**

469 To combine the attributes of the first two calculation methods (Calculation 1 and 2), an approach
 470 using homogeneity of response for three subgroups of GHS Category 1 substances was
 471 considered. Based on the three subgroups defined in **Section 2.0**, the distribution of response in
 472 each subgroup is summarized in **Table C** in **Appendix B**. The estimated underclassification
 473 likelihood can be calculated as previously described; these probabilities are summarized in **Table**
 474 **5.**

475

476 **3.4 Subsets of GHS Category 1 Substances**

477 Estimated underclassification likelihoods were calculated for various subsets of GHS Category 1
 478 substances in the database (e.g., the four different GHS criteria used to identify a corrosive or
 479 severe irritant or corrosive, liquids/gels versus solids, selected chemical classes).

480

481 **3.4.1 GHS Criteria Used to Identify Corrosives and Severe Irritants**

482 One set of analyses compared the four subgroups that were created by NICEATM² for GHS
 483 Category 1 substances, based on the type of response observed in the rabbits that led to
 484 classification of the test substance as a corrosive or severe irritant according to the GHS

485

² These are not formal subgroups defined by the GHS (UN 2003), but rather were created by NICEATM for the purpose of this analysis.

485 **Table 5. Estimated Underclassification Likelihoods for Three Subgroups of GHS**
 486 **Category 1 Substances using Calculation 3 (Assumes Homogeneity of**
 487 **Response Within Categories)**

Category	Strong Responders	Moderate Responders	Weak Responders	Overall Underclassification Likelihood ¹
GHS Category 2A	0.0000	0.0587	0.2934	0.0768
GHS Category 2B	0.0000	0.0149	0.1126	0.0281
GHS Nonirritants	0.0000	0.0010	0.0188	0.0044
Variable Responders	0.0000	0.0016	0.0112	0.0028
Total	0.0000 (0.00%)	0.0762 (7.62%)	0.4360 (43.60%)	0.1121 (11.21%)

488 See Table C in Appendix B for the distribution of rabbit responses used to assess underclassification likelihood for
 489 GHS Category 1 substances (Calculation 3).

490 Strong responders are GHS Category 1 substances that produced either a Cat 1A or 1B response in all tested rabbits;
 491 Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of
 492 the rabbits tested; Weak responders are GHS Category 1 substances that produced a nonsevere irritant (i.e., Cat 2A
 493 or 2B) or nonirritant response in more than half of the rabbits tested.

494 ¹Overall Underclassification Likelihood calculated as an average based on the prevalence of substances within the
 495 three responder categories.

496

497 classification system (UN 2003). These criteria (1 through 4) are:

- 498 • *Criterion 1*: Positive response not based on severity but on persistent lesion involving
 499 cornea, iris, and/or conjunctiva through to day 21 in at least one of three rabbits
- 500 • *Criterion 2*: Positive response based on mean score for first three days (corneal opacity
 501 ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits but lesions do not persist through
 502 day 21
- 503 • *Criterion 3*: Positive response based on mean for first three days (corneal opacity ≥ 3 and
 504 < 4 or iritis ≥ 1.5) in at least two of three rabbits and lesions in at least one of three rabbits
 505 that persist through day 21
- 506 • *Criterion 4*: Corneal opacity equal to 4 at any time in at least one of three rabbits

507

508 The distribution of animal responses for GHS Category 1 substances classified according to each
 509 of the four GHS criteria are provided in Tables D and E in Appendix B. Using the three
 510 calculation methods described in Section 2.0, a range of estimated underclassification
 511 likelihoods were calculated for each GHS Category 1 criterion using the previously described
 512 calculations (Table 6).

513 **Table 6. Estimated Underclassification Likelihoods for GHS Category 1 Substances in the Total Database Distinguished**
 514 **by the GHS Criterion used to Classify the Test Substance as a Corrosive or Severe Irritant**

Category	Calculation 1				Calculation 2				Calculation 3			
	Crit. 1	Crit. 2	Crit. 3	Crit. 4	Crit. 1	Crit. 2	Crit. 3	Crit. 4	Crit. 1	Crit. 2	Crit. 3	Crit. 4
GHS Category 2A	0.0528	0.0058	0.0000	0.0042	0.0907	0.0156	0.0000	0.0236	0.0900	0.0299	0.0000	0.0232
GHS Category 2B	0.0308	0.0020	0.0000	0.0010	0.0747	0.0324	0.0000	0.0159	0.0516	0.0124	0.0000	0.0097
GHS NI	0.0014	0.0000	0.0000	0.0007	0.0108	0.0000	0.0000	0.0135	0.0036	0.0000	0.0000	0.0059
VR	0.0002	0.0000	0.0000	0.0002	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0000	0.0003
Total	0.0852 (8.52%)	0.0078 (0.78%)	0.0000 (0.0%)	0.0061 (0.61%)	0.1762 (17.62%)	0.0480 (4.80%)	0.0000 (0.0%)	0.0530 (5.30%)	0.1452 (14.52%)	0.0423 (4.23%)	0.0000 (0.0%)	0.0391 (3.91%)

515 Abbreviations: Crit. = criterion; NI = Nonirritant; VR = variable responder

516 See **Tables D** and **E** in **Appendix B** for the distribution of rabbit responses used to assess underclassification likelihood for GHS Category 1 substances
 517 distinguished by GHS criterion used to classify corrosives or severe irritants.

518 Criterion 1: Positive response based not on severity but on persistent lesion involving cornea, iris, and/or conjunctiva through to day 21 in at least one of
 519 three rabbits; Criterion 2: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits
 520 but lesions do not persist through day 21; Criterion 3: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in
 521 at least two of three rabbits and lesions in at least one of three rabbits that persist through day 21; Criterion 4: Corneal opacity equal to 4 at any time in
 522 at least one of three rabbits.

523 Calculation 1 = homogeneity of response for GHS Category 1 irritants; Calculation 2 = heterogeneity of response for GHS Category 1 irritants; Calculation 3 =
 524 homogeneity of response for three subgroups of GHS Category 1 irritants.

526 Based on these analyses, the GHS Category 1 criterion with the lowest estimated
 527 underclassification likelihood was for substances that were classified as corrosives or severe
 528 irritants based on criteria 2 or 3. In contrast, the GHS Category 1 criterion with the highest
 529 estimated underclassification likelihood was for substances that were classified as corrosives or
 530 severe irritants based on criterion 1.

531

532 **3.4.2 Liquids/Gels versus Solids**

533 Another evaluation conducted was based on the physical form of the test substances (i.e., solids
 534 versus liquids/gels). The distributions of data in the total database, by physical property, are
 535 provided in **Tables F and G in Appendix B**. Using the three calculation methods described in
 536 **Section 2.0**, a range of estimated underclassification likelihoods were calculated for each
 537 liquids/gels and solids using the previously described calculations (**Table 7**).

538

539 **Table 7. Estimated Underclassification Likelihoods for GHS Category 1 Substances in**
 540 **the Total Database Tested as Liquids/Gels or Solids**

Category	Calculation 1		Calculation 2		Calculation 3	
	Liquid/Gel	Solids	Liquid/Gel	Solids	Liquid/Gel	Solid
GHS Category 2A	0.0326	0.2737	0.0862	0.0704	0.0840	0.0713
GHS Category 2B	0.0179	0.0004	0.0561	0.0108	0.0455	0.0013
GHS Nonirritant	0.0011	0.0001	0.0156	0.0019	0.0033	0.0010
Variable Responder	0.0020	0.0010	0.0000	0.0000	0.0035	0.0015
Total	0.0536 (5.36%)	0.0275 (2.75%)	0.1579 (15.79%)	0.0831 (8.31%)	0.1363 (13.63%)	0.0751 (7.51%)

541 See **Tables F and G in Appendix B** for the distribution of rabbit responses used to assess underclassification
 542 likelihood for GHS Category 1 substances, based on physical form.

543 Calculation 1 = homogeneity of response for GHS Category 1 irritants; Calculation 2 = heterogeneity of response
 544 for GHS Category 1 irritants; Calculation 3 = homogeneity of response for three subgroups of GHS Category 1
 545 irritants.

546

547 Although the estimated underclassification likelihoods for liquids/gels were a few percentage
 548 points higher than those calculated for solids, these differences are not significant, as determined
 549 by the Mann-Whitney U-test.

550

551 3.4.3 Subsets of GHS Category I Substances, based on Chemical Class

552 Another set of analyses compared the estimated underclassification likelihoods for GHS
553 Category I substances based on chemical class. For the total database, the number of studies in
554 each chemical class and the number of rabbits in each GHS Category are provided in **Table H** in
555 **Appendix B**. Because the small numbers of studies per chemical class for many of the
556 substances makes it difficult to assess whether or not heterogeneity is present within a given
557 chemical class, a single homogeneous calculation (Calculation 1) was conducted for the
558 chemical classes judged to have sufficient data (a minimum of 25 animals). The homogeneity
559 approach was considered reasonable because the data suggest that one important factor
560 contributing to the heterogeneity in the overall database is that some chemical classes are
561 associated with lower variability in responses among tested rabbits. The results of the estimated
562 underclassification likelihood calculations for the 12 chemical classes with 25 or more rabbits
563 (formulations, organic compounds, alcohols, amines, carboxylic acids, salts, ethers, esters,
564 heterocyclics, phenols, inorganics, and onium compounds) are provided in **Table 8**.

565

566 The estimated underclassification likelihoods for six (formulations, organic compounds,
567 alcohols, salts, ethers, esters) of the 12 chemical classes analyzed were similar to each other and
568 within the range of underclassification likelihoods estimated for the total database; these
569 likelihoods ranged from 4.68% for formulations to 10.89% for alcohols. Among the remaining
570 six chemical classes analyzed, the estimated underclassification likelihoods for five classes were
571 relatively low (0.00% for onium compounds and phenols, 0.48% for inorganics, 2.45% for
572 amines, 2.51% for heterocyclics) while the estimated underclassification likelihood for
573 carboxylic acids (16.64%) was higher.

574 **Table 8. Estimated Underclassification Likelihoods for GHS Category 1 Substances in**
 575 **the Total Database, Based on Chemical Class**

	Formulations	Alcohols	Amines	Organic Compounds	Carboxylic acids	Salts
Number of Studies	62	23	22	21	19	19
Number of Rabbits	306	89	81	68	66	65
GHS Category 2A	0.0286	0.0979	0.0228	0.0562	0.0891	0.0647
GHS Category 2B	0.0153	0.0035	0.0008	0.0175	0.0567	0.0095
GHS Nonirritant	0.0013	0.0020	0.0003	0.0092	0.0072	0.0095
Variable Responder	0.0016	0.0055	0.0006	0.0103	0.0140	0.0039
Total	0.0468 (4.68%)	0.1089 (10.89%)	0.0245 (2.45%)	0.0932 (9.32%)	0.1664 (16.64%)	0.0876 (8.76%)

576

	Ethers	Esters	Heterocycles	Phenols	Inorganics	Onium compounds
Number of Studies	11	10	12	6	7	9
Number of Rabbits	39	37	37	31	29	29
GHS Category 2A	0.0467	0.0213	0.0090	0.0000	0.0048	0.0000
GHS Category 2B	0.0248	0.0272	0.0161	0.000	0.0000	0.0000
GHS Nonirritant	0.0012	0.0000	0.0000	0.0000	0.0000	0.0000
Variable Responder	0.0033	0.0000	0.0000	0.0000	0.0000	0.0000
Total	0.0760 (7.60%)	0.0485 (4.85%)	0.0251 (2.51%)	0.0000 (0.0%)	0.0048 (0.48%)	0.0000 (0.0%)

577 See **Table H in Appendix B** for the distribution of rabbit responses used to assess underclassification likelihood for
 578 GHS Category 1 substances, based on chemical class. Estimated underclassification likelihoods based on
 579 Calculation 1, which assumes homogeneity of response among rabbits for GHS Category 1 irritants within a
 580 chemical class.

581 Chemical classes in table are ordered by decreasing number of rabbits tested.

582 Chemical class assignments are based on chemical structures; formulations are mixtures of chemicals, therefore
 583 individual chemical class assignments could not be made. Not all substances could be classified by chemical class
 584 and some substances were classified into more than one chemical class.

585 **4.0 Underclassification and Overclassification Likelihood Calculations for GHS**
 586 **Category 2A, 2B, and Nonirritant Substances**

587

588 **4.1 Calculation 1: Homogeneity of Response for GHS Category 2A, 2B, and Nonirritant**
 589 **Substances**

590 The distribution of rabbit responses for substances judged to be GHS Category 2A, 2B and
 591 nonirritants are given in **Table I** in **Appendix B**. Using this distribution of rabbits and the
 592 calculations previously described in **Section 3.1**, the estimated underclassification and
 593 overclassification likelihoods are provided (**Table 9**).

594

595 **Table 9. Estimated Overclassification and Underclassification Likelihoods for GHS**
 596 **Category 2A, 2B, and Nonirritant Substances Using Calculation 1 (Assumes**
 597 **Homogeneity of Response)**

Category	GHS Category 2A Substances	GHS Category 2B Substances	Nonirritant Substances
GHS Category 1	0.0770	0.0128	0.000
GHS Category 2A	0.8370 (correct classification)	0.0521	0.0008
GHS Category 2B	0.0595	0.8553 (correct classification)	0.0015
GHS Nonirritants	0.0157	0.0753	0.9977 (correct classification)
Variable Responders	0.0108	0.0045	0.0000
Overclassification as a Category 1 Substance Likelihood	0.0770 (7.7%)	0.0128 (1.28%)	0.0000 (0.00%)

598 See **Table I** in **Appendix B** for the distribution of rabbit responses used to assess overclassification and
 599 underclassification likelihoods for GHS Category 2A, 2B, and nonirritant substances (Calculation 1).

600

601 **4.2 Calculation 2: Heterogeneity of Response for GHS Category 2A, 2B, and**
 602 **Nonirritant Substances**

603 The pattern of rabbit responses observed for the individual GHS Category 2A, 2B, and
 604 nonirritant studies in the total database is provided in **Table J** in **Appendix B**. Based on these
 605 probabilities, the estimated correct classification, overclassification and underclassification
 606 likelihoods were calculated, using the heterogeneity assumption (see **Table 10**).

607

608 **Table 10. Estimated Overclassification and Underclassification Likelihoods for GHS**
 609 **Category 2A, 2B, and Nonirritant Substances Using Calculation 2 (Assumes**
 610 **Heterogeneity of Response)**

Category	GHS Category 2A Substances	GHS Category 2B Substances	Nonirritant Substances
GHS Category 1	0.0667	0.0082	0.0000

GHS Nonirritants	0.0490	0.1349	0.9808 (correct classification)
Variable Responders	0.0063	0.0000	0.0000
Overclassification as a Category 1 Substance Likelihood	0.0667 (6.67%)	0.0082 (0.82%)	0.0000 (0.00%)

611 See **Table J in Appendix B** for the distribution of rabbit responses used to assess overclassification and
 612 underclassification likelihoods for GHS Category 2A, 2B, and nonirritant substances (Calculation 2).
 613

613 **5.0 EQUIVOCAL SUBSTANCES**

614

615 In addition to the substances used in the statistical analyses described in **Sections 3.0 and 4.0**,
616 there were a total of 15 substances (less than 2% of the total) that could not be easily classified
617 based on the pattern of responses observed (i.e., there was no consensus response observed in the
618 rabbits tested). Therefore, they were excluded from the previously described analyses. Since
619 these substances (as well as some additional 2A and 2B substances that displayed severe
620 responses in a minority of the tested rabbits) could impact the underclassification likelihood
621 calculated for Category 1 substances, it was determined that additional analysis should be
622 conducted which included these substances.

623

624 For nine of the 15 substances, at least one animal in each study produced a Category 1A
625 response; for the remaining six substances the animal responses were divided between Category
626 2A, 2B, and nonirritants (**Table K in Appendix B**). It was determined that for the nine
627 substances where a Category 1A response was seen in a single animal, they would be reclassified
628 as Category 1 substances. This assumption was based on the observation that of all the rabbits
629 tested for the nonsevere irritants and nonirritants, 0.4% (9/2481) produced a Category 1A
630 response (see **Table I in Appendix B**). Comparatively, 69% (499/723) of the rabbits tested for
631 the severe irritants produced a Category 1A response (see **Table C in Appendix B**). Extending
632 this observation to substances originally classified as Category 2A and 2B substances, led to
633 eight Category 2A substances and one Category 2B substance being reclassified as Category 1.
634 This yielded a total of 18 substances being included into this analysis.

635

636 For this analysis, Calculation 3 was used to assess the impact of these additional 18 substances.
637 The distribution of animal responses for these 18 substances led each being classified as a “weak
638 responder” (see **Table L in Appendix B**). The distribution of rabbits within the three groups
639 (strong, moderate, and weak responders) are provided in **Table M in Appendix B**. The
640 estimated underclassification likelihoods for each of these subcategories are given below (**Table**
641 **11**).

642

642

643 **Table 11. Estimated Underclassification Likelihoods for Three Subgroups of GHS**
 644 **Category 1 Substances using Calculation 3 (Assumes Homogeneity of**
 645 **Response and including 18 Equivocal Substances)**

Category	Strong Responders	Moderate Responders	Weak Responders	Overall Likelihood	
				Total Database	Total Database (w/o 18 substances)
GHS Category 2A	0.0000	0.0587	0.3250	0.1058	0.0768
GHS Category 2B	0.0000	0.0149	0.0954	0.0307	0.0281
GHS Nonirritants	0.0000	0.0010	0.0676	0.0202	0.0044
Variable Responders	0.0000	0.0016	0.0125	0.0040	0.0028
Total	0.0000 (0.00%)	0.0762 (7.62%)	0.5005 (50.05%)	0.1607 (16.07%)	0.1121 (11.21%)

646 See Table M in Appendix B for the distribution of rabbit responses used to assess underclassification likelihood
 647 (Calculation 3).

648 Strong responders are GHS Category 1 substances that produced either a Cat 1A or 1B response in all tested rabbits;
 649 Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of
 650 the rabbits tested; Weak responders are GHS Category 1 substances that produced a nonsevere irritant (i.e., Cat 2A
 651 or 2B) or nonirritant response in more than half of the rabbits tested.

652

652 **6.0 MODIFIED SPRINGER ANALYSIS AS APPLIED TO THE *IN VIVO* OCULAR
653 TOXICITY DATABASE**

654

655 One limitation of the preceding underclassification likelihood analysis is that it requires an *a*
656 *priori* assignment of each chemical to a specific irritation classification category (GHS Category
657 I, 2A, 2B or nonirritant). Since there is little or no human data upon which to base this
658 classification, this assignment was based on the results of the *in vivo* rabbit eye test itself. As a
659 consequence, there is a circularity in using the results of *in vivo* rabbit eye studies as the basis for
660 estimating the over- and under-classification likelihoods associated with the same test. Thus, an
661 alternative approach was sought that did not require this *a priori* assignment of chemicals to
662 classification categories.

663

664 Springer et al. (1993) proposed one such approach. This methodology has limitations of its own
665 in that it assumes only two responses (irritant and nonirritant) and also assumes a fixed number
666 of animals (e.g., the number of animals tested per study is 6). Importantly, the Springer et al.
667 methodology assumes a binomial distribution of responses for both irritants and nonirritants (i.e.,
668 no heterogeneity of response). This assumption is violated in data for the irritants used in the
669 underclassification likelihood analysis.

670

671 Specifically, the Springer approach estimates three parameters that provide the best fit to the
672 observed data:

673 pn: the proportion of nonirritants in the database

674 pi+: the likelihood of an irritant producing a positive response

675 pn+: the likelihood of a non-irritant producing a positive response.

676

677 The Springer model is essentially a mixture of two binomial distributions, with the relative
678 frequency of nonirritants being one of the three parameter estimated (pn). Thus, within the
679 irritant and nonirritant categories, the expected distribution of outcomes can be calculated based
680 on the usual binomial model probabilities (pi+ for irritants; pn+ for non-irritants). For example,
681 for a six animal test, the expected likelihood of an irritant producing 6/6 positive responses is
682 simply $(\text{pi}^+)^6$. The corresponding likelihood of a 5/6 response is $6x(\text{pi}^+)^5x(1-\text{pi}^+)$. Other

683 expected binomial frequencies can be calculated in a similar manner. Estimates of the
 684 parameters p_n , p_{i+} , and p_{n+} that provide the best fit to the observed data can then be obtained by
 685 minimizing the Chi-Square Goodness of fit test statistic that compares the observed and expected
 686 distribution of outcomes.

687

688 The application of the Springer et al. methodology to the NICEATM *in vivo* rabbit eye test
 689 database was evaluated. To accommodate the two response categories used by Springer et al.,
 690 the data were collapsed into two irritation categories (GHS Category 1 substances were classified
 691 as irritants and GHS Category 2A, 2B and nonirritants were classified as nonirritants). As with
 692 Springer et al., the studies used for the evaluation was limited to those that tested six rabbits;
 693 these studies represented 38% (303/792) of the studies available. The distribution of all six
 694 rabbit outcomes in the database is provided in **Table 12**.

695

696 **Table 12. Distribution of Studies Based on the Number of Rabbits Producing an**
 697 **Irritant (GHS Category 1) Response**

Number Irritant (GHS Category 1) Rabbits/ Total Rabbits Evaluated	Frequency
6/6	34
5/6	8
4/6	6
3/6	7
2/6	15
1/6	21
0/6	212
Total	303

698

699 The Springer et al. approach assumes that this distribution represents a mix of irritants and
 700 nonirritants. It estimates three parameters that provide the best fit to these data: (1) the
 701 proportion of nonirritants in the database; (2) the likelihood of an irritant producing a positive
 702 response; and (3) the likelihood of a nonirritant producing a positive response. An application of
 703 the Springer method to the data above produces the following parameter estimates:

704

704 *Proportion of nonirritants in the database = 80.1%*

705 *Probability of a positive response for an irritant = 85.6%*

706 *Probability of a positive response for a non-irritant = 4.6%*

707

708 The fit produced by the Springer et al. model is provided below (**Table 13**). As can be seen from
 709 the analysis, the expected total does not fit well with the observed values. The reason for the
 710 poor fit is that the irritant database has extra-binomial variation (i.e., is not homogeneous), so the
 711 Springer et al. model under-estimates the observed variability in response. Because of this, the
 712 underclassification likelihood resulting from an application of the Springer et al. method is rather
 713 low (i.e., $(1-.856)(1-.856)(1-.856)$ or 0.3%).

714

715 **Table 13. Results of Analysis Based on the Springer et al. Approach**

Number Irritant (GHS Category 1) Rabbits/Total Rabbits Evaluated	Expected			Observed
	Irritants	Nonirritants	Total	
6/6	23.72	0.00	23.72	34
6/5	23.94	0.00	23.94	8
4/6	10.07	0.01	10.08	6
3/6	2.26	0.41	2.67	7
2/6	0.28	6.38	6.67	15
1/6	0.02	52.93	52.95	21
0/6	0.00	182.96	182.96	212
Total	60.29	242.69	302.99	303

716

717 To address this deficiency, the Springer et al. approach was modified to take into account the
 718 heterogeneity observed in the database. Following the same reasoning used previously in the
 719 application of Approach 3, it was assumed that the irritants are not homogeneous but instead are
 720 a mix of two homogeneous subcategories: strong and weak irritants. Thus, this “modified
 721 Springer method” estimates five parameters rather than three. These parameters are:

722 pn: the proportion of nonirritants in the database

723 psi: the proportion of strong irritants in the database

724 psi+: the likelihood of a strong irritant producing a positive response

725 pwi+: the likelihood of a weak irritant producing a positive response

726 pn+: the likelihood of a nonirritant producing a positive response

727

728 Application of the modified Springer method to the data is summarized in **Table 14**.

729

730 **Table 14. Results of Analysis Based on a Modified Springer et al. Approach**

Number Irritant (GHS Category 1) Rabbits/Total Rabbits Evaluated	Expected				Observed
	Strong Irritants	Weak Irritants	Nonirritants	Total	
6/6	33.6	0.1	0.0	33.7	34
6/5	7.5	0.9	0.0	8.4	8
4/6	0.7	4.0	0.0	4.7	6
3/6	0.0	9.8	0.0	9.8	7
2/6	0.0	13.5	0.3	13.8	15
1/6	0.0	9.9	11.2	21.1	21
0/6	0.0	3.0	208.5	211.5	212
Total	41.8	41.2	220.0	303.0	303

731

732 The specific parameter estimates are:

733 *Proportion of nonirritants in the database = 72.6%.*

734 *Proportion of strong irritants in the database=13.8%*

735 *Proportion of weak irritants in the database=13.6% (100%-72.6%-13.8%)*

736 *Probability of a positive response for a strong irritant = 96.4%*

737 *Probability of a positive response for a weak irritant = 35.3%*

738 *Probability of a positive response for a nonirritant = 0.89%*

739

740 Thus, the modified Springer approach estimates that the irritants (i.e., corrosives and severe
741 irritants) are roughly a 50-50 mix of strong and weak irritants. The estimated underclassification
742 rate for the modified Springer approach is essentially zero for strong irritants and $(1-0.353)(1-0.353)$ or 27.08% for weak irritants. Taking into account the relative distribution of
743 strong and weak irritants, the overall estimated underclassification rate for all irritants is 13.4%,
744

745 which agrees closely with our estimate using all the data and not collapsing the classifications.

746

747 Using the modified Springer approach, the estimated overclassification rate for a nonirritant (i.e.,
748 nonsevere irritants and nonirritants) as an irritant (i.e., corrosives and severe irritants) is simply
749 the likelihood of observing one positive response in the three animal sequential test, which,
750 based on the parameter estimates above is $1-(.9911)^3$ or 2.65%, which is slightly higher than the
751 corresponding overclassification estimate of less than 1% based on the previous approach.

769

769 **7.0 SUMMARY**

770

771 This report estimates the potential for substances to be misclassified based on evaluating the
772 variability in the observed rabbit responses. The two overall analyses that were conducted were:
773 (1) an assessment of the underclassification likelihood of ocular corrosives/severe irritants being
774 classified as nonsevere irritants/nonirritants; and (2) an assessment of the overclassification
775 likelihood of ocular nonsevere irritants/nonirritants being classified as corrosives/severe irritants.
776 The GHS classification system was used because it has been internationally harmonized through
777 the UN and is expected to be implemented globally in the future. Within the first overall
778 underclassification analysis, additional analyses were conducted to determine the impact of
779 physical form, chemical class, and GHS criteria for classification on the underclassification
780 likelihood of corrosives/severe irritants.

781

782 The estimated underclassification likelihoods obtained using the three different calculation
783 methods that were based on the hazard classification category assigned to a test substance from
784 the results of the *in vivo* rabbit eye test study are summarized in **Table 15**. As discussed
785 previously, Calculation 1 assumes homogeneity of response within an irritancy category. While
786 this simplifies the computation, it ignores the potentially significant contribution of animal
787 variability to the underclassification likelihood. Calculation 2 assumes heterogeneity of response
788 within an irritancy category, which leads to a higher estimated likelihood than determined by
789 Calculation 1. One significant limitation of this approach is that the distribution of observed
790 rabbit responses for each substance is based on a small number of rabbits. Calculation 3
791 attempts to incorporate aspects of both Calculation 1 and 2. Calculation 2 likely provides the
792 most reasonable estimate of the underclassification likelihood for GHS Category 1 substances.

793

794 Using the three calculation methods, the estimated underclassification likelihoods for the total
795 database ranged from 4.30% for Calculation 1 to 11.21% for Calculation 3 to 13.24% for
796 Calculation 2. For all three calculation methods, the greatest contribution to the
797 underclassification likelihood comes from a Category 1 substances being classified as a Category
798 2A (likelihoods range from 3.00% to 7.68% depending on the calculation method).

799

799 **Table 15. Overall Estimated Underclassification Likelihoods for GHS Category 1**
 800 **Substances in the Total Database**

Classification	Calculation 1	Calculation 2	Calculation 3	Springer-Type Analysis
Category 2A	3.00%	7.51%	7.68%	n.a.
Category 2B	0.94%	4.29%	2.81%	n.a.
Nonirritants	0.12%	1.44%	0.44%	n.a.
Variable Responders	0.24%	0.005	0.28%	n.a.
Total	4.30%	13.24%	11.21%	13.4%

801 Abbreviation: n.a. = not applicable.

802 Calculation 1 = homogeneity of response for GHS Category 1 irritants; Calculation 2 = heterogeneity of response
 803 for GHS Category 1 irritants; Calculation 3 = homogeneity of response for three subgroups of GHS Category 1
 804 irritants.

805

806 One of the factors that impacted the estimated underclassification likelihood was the presence of
 807 substances that could not be classified according to the GHS classification system (i.e., the
 808 Variable Responder Category). In the testing strategy used to mimic a three-animal sequential
 809 test, two different outcomes could lead to an equivocal GHS classification. Under normal testing
 810 circumstances, it is likely that additional animals would be sequentially tested in order to arrive
 811 at a definitive classification. However, because this is a retrospective analysis, testing another
 812 animal is not feasible. Therefore, this category was used to assess the likelihood that more than
 813 three animals would need to be evaluated when testing a severe irritant. As shown in **Table 15**,
 814 this value is small (0.00% to 0.3%).

815

816 Another factor that likely increased the estimated underclassification likelihood was the
 817 inclusion of substances, based on the animal responses, which were not classified as GHS
 818 Category 1 irritants. These studies represented substances that produced a GHS Category 1
 819 classification at one concentration but in a nonsevere classification when tested at a higher
 820 concentration. These studies were included in the database under the assumption that with
 821 increasing concentration, the same or a more severe response would be expected. It is
 822 recognized that a bell-shaped dose response curve may occur for some substances (e.g.,
 823 polymerization at higher concentrations may lead to decreased bioavailability). However, since
 824 the mode of action of all of these substances was not known, it was decided to reclassify all such
 825 studies as corrosives/severe irritants. By including these studies, greater variability was

826 incorporated into the database which, in turn, increased the underclassification likelihood for all
 827 three calculation methods.

828

829 By including 18 substances that were previously not classified or classified as nonsevere irritants
 830 as severe irritants, the impact of including variability into the analysis can be demonstrated. As
 831 shown in **Table 16**, the inclusion of these substances increased that underclassification
 832 likelihood from 11.21% to 16.07%.

833

834 **Table 16. Estimated Underclassification Likelihoods for Three Subgroups of GHS**
 835 **Category 1 Substances using Calculation 1 (Assumes Homogeneity of**
 836 **Response; including 18 Equivocal Substances)**

Category	Total Database (w/18 substances)	Total Database (w/o 18 substances)
GHS Category 2A	10.58%	7.68%
GHS Category 2B	3.07%	2.81%
GHS Nonirritants	2.02%	0.44%
Variable Responders	0.40%	0.28%
Total	16.07%	11.21%

837

838 It is fully appreciated that using data for substances already classified as corrosive or severely
 839 irritating based on a single study only might introduce a bias in the analysis (i.e., result in an
 840 underestimate of the underclassification likelihood). However, considering the relatively large
 841 numbers of studies involved, the fact that they originate from multiple laboratories across several
 842 decades of testing, and that there is a reasonable expectation that some of the substances included
 843 in this database represent those that might have been classified as nonsevere irritants in a
 844 different study, we consider these estimates a reasonable reflection of the true underclassification
 845 potential using the current three animal sequential testing procedure for identifying ocular
 846 corrosives and severe irritants, as defined by the GHS hazard classification system (UN 2003).

847

848 Using the modified Springer approach, the overall estimated underclassification rate for all
 849 irritants is 13.4% (see **Table 15**). This value agrees closely with the previous estimate using all
 850 the data, and not collapsing the classifications. One issue with the Springer-type analysis is how
 851 representative the studies where six rabbits were evaluated are of the entire database. In this

852 regard, it is noted that the estimated proportion of irritants in the database using the modified
853 Springer method (13.8+13.6 or 27.4%) is similar to our empirical estimate based on the entire
854 database and our assignment of chemicals to irritation categories ($181/792 = 22.9\%$). Whether or
855 not studies where six animals were tested represented the entire database would be of greater
856 importance if the resulting estimated underclassification likelihoods were not so similar (**Table**
857 **15**).

858

859 Even though both approaches are very similar in the estimated proportion of irritants, it could be
860 argued that our empirical assignment of chemicals to irritant categories very slightly under-
861 estimated the true number of irritants, and if “corrected” by a re-assignment of a few chemicals
862 (which would necessarily be weak irritants) to the irritant database, the underclassification
863 likelihood would have been slightly increased. This hypothetical adjustment would make the
864 underclassification likelihoods from the preceding approach and the modified Springer approach
865 agree even more closely.

866

867 Since two totally different approaches, based on different underlying assumptions and different
868 sets of substances produce very similar estimates of the underclassification rates, it is proposed
869 that the true underclassification likelihoods for the rabbit test is likely to be in the 11-14% range.
870

871 In terms of the analysis of subsets of substances in the total database, an analysis was conducted
872 to estimate the underclassification likelihoods for:

- 873 • GHS Category 1 substances separated into four subcategories based on the GHS
874 criterion used to classify them as ocular corrosives or severe irritants.
875 • solids versus liquids/gels, and
876 • chemical classes that contained sufficient data for an analysis (i.e., at least 25 rabbits per
877 chemical class).

878

879 When evaluating the criteria for GHS Category 1 classification, the lowest estimated
880 underclassification likelihood (0.00%, for all calculation methods used) was for criterion 3 and
881 the highest estimated underclassification likelihood (8.52% to 17.62%, depending on the
882 calculation method used) was for GHS criterion 1. Caution should be taken when interpreting

883 results for criteria 2 and 3, since they are based on limited datasets. Comparison of the larger
884 datasets, indicate that the difference between criteria 1 and criteria 4 is significant ($p < 0.01$).
885

886 For solids versus liquids/gels, regardless of which of the three calculation methods was used, the
887 estimated underclassification likelihood for liquids/gels was a higher than that calculated for
888 solids. However, these differences were not statistically significant (using the Mann-Whitney U
889 test).

890

891 Because the small numbers of studies per chemical class make it difficult to assess whether or
892 not heterogeneity is present within a given chemical class, a single homogeneous calculation
893 (Calculation 1) was conducted for the 12 chemical classes judged to have sufficient data (≥ 25
894 rabbits). The estimated underclassification likelihoods for six of the 12 chemical classes
895 analyzed were similar to each other and within the range of underclassification likelihoods
896 estimated for the total database; these likelihoods ranged from 4.68% for formulations to 10.89%
897 for alcohols. Among the remaining six chemical classes analyzed, the estimated
898 underclassification likelihoods for five classes were relatively low (0.00% for onium compounds
899 and phenols to 2.51% for heterocyclics) and the estimated underclassification likelihood for
900 carboxylic acids (16.64%) was relatively high. The low estimated underclassification
901 likelihoods suggests that the rabbit ocular response to GHS Category 1 substances in these
902 chemical classes are relatively consistent, while the high estimated underclassification likelihood
903 for carboxylic acids suggests that the rabbit ocular responses to GHS Category 1 substances in
904 this chemical class are more likely to be variable.

905

906 The estimated overclassification likelihoods for nonsevere irritants and nonirritant substances as
907 Category 1 substances are summarized in **Table 17**. As in **Table 15**, Calculation 1 assumes
908 homogeneity of response while Calculation 2 assumes heterogeneity of response.
909

910 As is seen in **Table 17**, the likelihood of overclassification decreases as the irritancy of the
911 substances decreases (i.e., 7.70% for Category 2A substances and 0.00% for nonirritant
912 substances). This is not unexpected considering the greatest variability in responses and
913

913 **Table 17. Overall Estimated Overclassification Likelihoods for GHS Category 2A and**
 914 **2B Irritants and Nonirritant Substances**

Classification	GHS Category 2A		GHS Category 2B		Nonirritants		Springer-Type Analysis
	Calc. 1	Calc. 2	Calc. 1	Calc. 2	Calc. 1	Calc. 2	
Category 1	7.70%	6.67%	1.28%	0.82%	0.00%	0.00%	n.a.
Category 2A	<i>83.70%</i>	<i>75.41%</i>	5.21%	4.08%	0.08%	0.47%	n.a.
Category 2B	5.95%	12.39%	<i>85.53%</i>	<i>81.60%</i>	0.15%	1.45%	n.a.
Nonirritants	1.57%	4.90%	7.53%	13.49%	99.77%	98.08%	n.a.
Variable Responders	1.08%	0.63%	0.45%	0.00%	0.00%	0.00%	n.a.
Overclassification as a Category 1 Substance Likelihood	7.70%	6.67%	1.28%	0.82%	0.00%	0.00%	2.65%

915 Abbreviation: Calc. = Calculation; n.a. = not applicable.

916 Calculation 1 = homogeneity of response for GHS Category 1 irritants; Calculation 2 = heterogeneity of response
 917 for GHS Category 1 irritants.

918 Italicized text represents the likelihood of correct classification for the irritancy category noted.

919

920 classification are typically observed around the transition between irritancy categories (i.e.,
 921 Category 1 and 2A). Additionally, when the number of substances within these groups
 922 compared to the entire database (prevalence) are incorporated into the evaluation it is estimated
 923 that the overall likelihood of overclassifying a GHS Category 2A, 2B or nonirritant as a Category
 924 1 substance is <1%. Using the modified Springer approach, the overall estimated
 925 overclassification rate for all non-irritants is 2.65% (see **Table 17**). This value agrees with the
 926 previous estimate using all the data, and not collapsing the classifications.

927

928 These results indicate that the *in vivo* rabbit eye test method is repeatable at the extreme irritancy
 929 range (i.e., ocular corrosive or severe irritants) with an underclassification rate between 11% and
 930 14%; the greatest contribution to the underclassification rate occurs by Category 1 substances
 931 being underclassified as Category 2A irritants (3.00% to 7.68%). While the goal of future
 932 studies should focus on reducing the number of rabbits tested to assess ocular irritancy, and
 933 eventually replacing the *in vivo* rabbit eye test, any proposed *in vitro* ocular test method should
 934 strive to ensure that it meets or improves upon the performance of the *in vivo* rabbit eye test in
 935 identifying ocular corrosives and severe irritants.

Table C. Distribution of Rabbits Among Three Subgroups of GHS Category 1 Substances

	All Data	Strong Responders	Moderate Responders	Weak Responders
Number of Studies	181	108	32	41
Total Number of Rabbits	723	385	162	176
Cat 1A	499	347	104	48
Cat 1B	50	38	6	6
Cat 2A	96	0	32	64
Cat 2B	58	0	16	42
Nonirritant	20	0	4	16

Abbreviation: Cat = Category

Strong responders are GHS Category 1 substances that produced either a Cat 1A or 1B response in all tested rabbits; Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of the rabbits tested; Weak responders are GHS Category 1 substances that produced a nonsevere irritant (i.e., Cat 2A or 2B) or nonirritant response in more than half of the rabbits tested.

Table D. Distribution of Studies and Rabbits (Total and by Responder Classification) for GHS Category 1 Substances Categorized into the Four GHS Criteria for Classifying a Test Substance as a Corrosive or Severe Irritant

	Criterion 1				Criterion 2				Criterion 3				Criterion 4			
	Total	Strong	Mod.	Weak												
Number of Studies	61	22	18	21	8	6	2	0	3	3	0	0	88	68	11	9
Total Number of Rabbits	246	67	92	87	37	30	7	0	12	12	0	0	360	267	57	36
Cat 1A	156	66	61	29	3	2	1	0	8	8	0	0	315	262	41	12
Cat 1B	1	1	0	0	32	28	4	0	4	4	0	0	5	5	0	0
Cat 2A	46	0	17	29	1	0	1	0	0	0	0	0	21	0	11	10
Cat 2B	36	0	13	23	1	0	1	0	0	0	0	0	10	0	2	8
NI	7	0	1	6	0	0	0	0	0	0	0	0	9	0	3	6

Abbreviation: Cat = Category; Mod. = Moderate

Criterion 1: Positive response based not on severity but on persistent lesion involving cornea, iris, and/or conjunctiva through to day 21 in at least one of three rabbits; Criterion 2: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits but lesions do not persist through day 21; Criterion 3: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits and lesions in at least one of three rabbits that persist through day 21; Criterion 4: Corneal opacity equal to 4 at any time in at least one of three rabbits. Strong responders are GHS Category 1 substances that virtually always produce either a Cat 1A or 1B response in all tested rabbits; Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of the rabbits tested; Weak responders are GHS Category 1 substances that resulted in more than half of the rabbits tested responding with a Cat 2A, 2B, or nonirritant response.

**Table E. Distribution of Rabbit Response Patterns for GHS Category 1 Substances
Distinguished by the GHS Criterion used to Classify the Test Substance as a
Corrosive or Severe Irritant and the Corresponding Likelihood of
Classification**

Distribution of Rabbit Outcomes					Number of Studies				Likelihood of GHS Classification

Abbreviations: Cat = Category; Crit. = criterion; NI = Nonirritant; VR = variable responder.

Criterion 1: Positive response based not on severity but on persistent lesion involving cornea, iris, and/or conjunctiva through to day 21 in at least one of three rabbits; Criterion 2: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits but lesions do not persist through day 21; Criterion 3: Positive response based on mean for first three days (corneal opacity ≥ 3 and < 4 or iritis ≥ 1.5) in at least two of three rabbits and lesions in at least one of three rabbits that persist through day 21; Criterion 4: Corneal opacity equal to 4 at any time in at least one of three rabbits.

Table F. Distribution of GHS Category 1 Substances and Rabbits (Total and Total and by Responder Classification) for GHS Category 1 Substances Tested as Liquids/Gels or as Solids

	Liquids/Gels				Solids			
	Total	Strong	Moderate	Weak	Total	Strong	Moderate	Weak
Number of Studies	100	55	20	25	30	20	6	4
Total Number of Rabbits	420	207	100	113	120	74	30	18
Cat 1A	283	194	61	28	86	61	20	5
Cat 1B	22	13	4	5	16	13	2	1
Cat 2A	57	0	17	40	17	0	7	10
Cat 2B	47	0	15	32	2	0	1	1
NI	11	0	3	8	1	0	0	1

Abbreviations: Cat = Category; NI = Nonirritant

Strong responders are GHS Category 1 substances that virtually always produce either a Cat 1A or 1B response in all tested rabbits; Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of the rabbits tested; Weak responders are GHS Category 1 substances that resulted in more than half of the rabbits tested responding with a Cat 2A, 2B, or nonirritant response.

Table G. Distribution of Rabbit Response Patterns for GHS Category 1 Substances for Liquids/Gels and Solids, and the Likelihood of GHS Classification

* Chemical class assignments are based on chemical structures; formulations are mixtures of chemicals, therefore individual chemical class assignments could not be made. Not all substances could be classified by chemical class and some substances were classified into more than one chemical class.

Chemical classifications made based on the Medical Subject Headings (MeSH) chemical classification system (<http://www.nlm.nih.gov/mesh/meshhome.html>).

Table I. Distribution of Rabbits for GHS Category 2A, 2B, and Nonirritant Substances

	Category 2A Substances	Category 2B Substances	Nonirritant Substances
Total Number of Studies	60	51	485
Total Number of Rabbits Classified as Cat 1A	8	1	0
Total Number of Rabbits Classified as Cat 1B	7	1	0

Abbreviations: Cat = Category, NI = Nonirritant, VR = variable responder.

Table M. Distribution of Rabbits Among Three Subgroups of GHS Category 1 Substances After Inclusion of 18 Additional Substances

	All Data	Strong Responders	Moderate Responders	Weak Responders
Number of Studies	199	108	32	59
Total Number of Rabbits	829	385	162	282
Cat 1A	517	347	104	66
Cat 1B	50	38	6	6
Cat 2A	134	0	32	102
Cat 2B	76	0	16	60
Nonirritant	52	0	4	48

Abbreviation: Cat = Category

Strong responders are GHS Category 1 substances that produced either a Cat 1A or 1B response in all tested rabbits; Moderate responders are GHS Category 1 substances that produced a Cat 1 response in at least 50% but not 100% of the rabbits tested; Weak responders are GHS Category 1 substances that produced a nonsevere irritant (i.e., Cat 2A or 2B) or nonirritant response in more than half of the rabbits tested.
