3,3′-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

CAS No. 20325-40-0

$C_{14}H_{16}N_2O_2$•2HCl Molecular weight 317.2

Synonyms: *o*-dianisidine dihydrochloride; 3,3′-dimethoxy-(1,1-biphenyl)-4,4′-diamine dihydrochloride; 3,3′-dimethoxy-4,4′-diaminobiphenyl dihydrochloride

ABSTRACT

3,3′-Dimethoxybenzidine dihydrochloride was evaluated in toxicity and carcinogenicity studies as part of the National Toxicology Program's Benzidine Dye Initiative. This Initiative was designed to evaluate representative benzidine congeners and benzidine congener-derived and benzidine-derived dyes. 3,3′-Dimethoxybenzidine dihydrochloride was nominated for study because of the potential for human exposure during production of bisazobiphenyl dyes and because benzidine, a structurally related chemical, is a known human carcinogen.

Toxicology and carcinogenesis studies were conducted by administering 3,3′-dimethoxybenzidine dihydrochloride (greater than 97.5% pure) in drinking water to groups of F344/N rats of each sex for 14 days, 13 weeks, 9 months, or 21 months. The 21-month studies were intended to last 24 months but were terminated early because of rapidly declining survival due to neoplasia. Studies were performed only in rats because similar studies are being performed in mice at the National Center for Toxicology Research. Genetic toxicology studies were conducted with *Salmonella typhimurium*, Chinese hamster ovary (CHO) cells, and *Drosophila melanogaster*.

Fourteen-Day Studies: All rats receiving drinking water concentrations up to 4,500 ppm lived to the end of the studies. Rats that received water containing 4,500 ppm 3,3′-dimethoxybenzidine dihydrochloride lost weight. Water consumption decreased with increasing concentration of chemical and at 4,500 ppm was less than one-fourth that by the controls. Lymphoid depletion of the thymus in males and hypocellularity of the bone marrow in males and females were seen at the 4,500-ppm concentration, but not at the next lower concentration or in controls.

Thirteen-Week Studies: All rats receiving concentrations up to 2,500 ppm lived to the end of the studies. Final mean body weights of rats given drinking water containing 1,250 or 2,500 ppm 3,3′-dimethoxybenzidine dihydrochloride were 5%-20% lower than those of controls. Water consumption at these concentrations was 40%-60% that consumed by controls. Compound-related effects in rats given water containing 2,500 ppm 3,3′-dimethoxybenzidine dihydrochloride included a mild exacerbation of naturally occurring nephropathy and the presence of a yellow-brown pigment (lipofuscin) in the cytoplasm of thyroid follicular cells. Serum triiodothyronine (T_3) and thyroxin (T_4) concentrations in females receiving 330 ppm or more and T_4 concentrations in males receiving 170 ppm or more were significantly lower than in controls. Thyrotropin (TSH) concentrations were comparable in controls and exposed rats.

Based on the chemical-related nephropathy and reductions in water consumption and body weight gain observed in the 13-week studies, doses for the long-term studies in male and female rats were 0 or 330 ppm 3,3'-dimethoxybenzidine dihydrochloride in drinking water administered for 9 months and 0, 80, 170, or 330 ppm administered for 21 months.

Nine-Month Studies: Ten rats of each sex in the control and 330-ppm groups were evaluated after 9 months. Significant decreases in T_3 and T_4 concentrations were seen in exposed male and female rats. Other lesions seen in exposed rats included foci of alteration in the liver, a carcinoma of the preputial gland in one male, a carcinoma of the clitoral gland in one female, and carcinoma of the Zymbal gland in two males.

Body Weights and Survival in the Twenty-One-Month Studies: The average amount of 3,3'-dimethoxybenzidine dihydrochloride consumed per day was approximately 6, 12, or 21 mg/kg for low, mid, or high dose male rats and 7, 14, or 23 mg/kg for low, mid, or high dose female rats. Mean body weights of male and female rats began to decrease relative to those of controls after about 1 year of exposure at 170 or 330 ppm and were 6%-22% lower for males and 7%-17% lower for females. Survival of rats exposed to 3,3'-dimethoxybenzidine dihydrochloride was reduced because animals were dying with neoplasms or being killed in a moribund condition (survival at 21 months--male: control, 44/60, 73%; low dose, 8/45, 18%; mid dose, 0/75; high dose, 0/60; female: 45/60, 75%; 15/45, 33%; 6/75, 8%; 0/60). Because of these early compound-related deaths, the studies were terminated at 21 months.

Nonneoplastic and Neoplastic Effects in the Twenty-One-Month Studies: Increased incidences of several nonneoplastic lesions were observed in exposed rats, including hematopoietic cell proliferation in the spleen and cystic and centrilobular degeneration and necrosis of the liver. Neoplasms attributed to 3,3'-dimethoxybenzidine dihydrochloride exposure were observed in rats at many tissue sites, including the skin, Zymbal gland, preputial and clitoral glands, oral cavity, small and large intestines, liver, brain, mesothelium, mammary gland, and uterus/cervix. The incidences of these neoplasms in male and female rats are given in the abstract summary table.

Genetic Toxicology: 3,3'-Dimethoxybenzidine was mutagenic in *S. typhimurium* strain TA100 with exogenous metabolic activation and in strain TA98 without activation; a weakly positive response was observed in strain TA1535 with metabolic activation. 3,3'-Dimethoxybenzidine induced sister chromatid exchanges and chromosomal aberrations in CHO cells with and without exogenous metabolic activation. 3,3'-Dimethoxybenzidine did not induce sex-linked recessive lethal mutations in adult male *D. melanogaster* exposed via feeding or injection.

Conclusions: Under the conditions of these 21-month drinking water studies, there was *clear evidence of carcinogenic activity** of 3,3'-dimethoxybenzidine dihydrochloride for male F344/N rats, as indicated by benign and malignant neoplasms of the skin, Zymbal gland, preputial gland, oral cavity, intestine, liver, and mesothelium. Increased incidences of astrocytomas of the brain may have been related to chemical administration. There was *clear evidence of carcinogenic activity* of 3,3'-dimethoxybenzidine dihydrochloride for female F344/N rats, as indicated by benign and malignant neoplasms of the Zymbal gland, clitoral gland, and mammary gland. Increases in neoplasms of the skin, oral cavity, large intestine, liver, and uterus/cervix were also considered to be related to chemical administration of 3,3'-dimethoxybenzidine dihydrochloride.

---

*Explanation of Levels of Evidence of Carcinogenic Activity is on page 6.
A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 9.

SUMMARY OF THE TWENTY-ONE-MONTH DRINKING WATER STUDIES OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

Male F344/N Rats	Female F344/N Rats
Drinking water concentration	
0, 80, 170, or 330 ppm 3,3'-dimethoxybenzidine dihydrochloride	0, 80, 170, or 330 ppm 3,3'-dimethoxybenzidine dihydrochloride

(b) Number with lesion/total evaluated (percent incidence)

EXPLANATION OF LEVELS OF EVIDENCE OF CARCINOGENIC ACTIVITY

The National Toxicology Program describes the results of individual experiments on a chemical agent and notes the strength of the evidence for conclusions regarding each study. Negative results, in which the study animals do not have a greater incidence of neoplasia than control animals, do not necessarily mean that a chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a chemical is carcinogenic for laboratory animals under the conditions of the study and indicate that exposure to the chemical has the potential for hazard to humans. Other organizations, such as the International Agency for Research on Cancer, assign a strength of evidence for conclusions based on an examination of all available evidence including: animal studies such as those conducted by the NTP, epidemiologic studies, and estimates of exposure. Thus, the actual determination of risk to humans from chemicals found to be carcinogenic in laboratory animals requires a wider analysis that extends beyond the purview of these studies.

Five categories of evidence of carcinogenic activity are used in the Technical Report series to summarize the strength of the evidence observed in each experiment: two categories for positive results ("Clear Evidence" and "Some Evidence"); one category for uncertain findings ("Equivocal Evidence"); one category for no observable effects ("No Evidence"); and one category for experiments that because of major flaws cannot be evaluated ("Inadequate Study"). These categories of interpretative conclusions were first adopted in June 1983 and then revised in March 1986 for use in the Technical Reports series to incorporate more specifically the concept of actual weight of evidence of carcinogenic activity. For each separate experiment (male rats, female rats, male mice, female mice), one of the following quintet is selected to describe the findings. These categories refer to the strength of the experimental evidence and not to either potency or mechanism.

- **Clear Evidence of Carcinogenic Activity** is demonstrated by studies that are interpreted as showing a dose-related (i) increase of malignant neoplasms, (ii) increase of a combination of malignant and benign neoplasms, or (iii) marked increase of benign neoplasms if there is an indication from this or other studies of the ability of such tumors to progress to malignancy.

- **Some Evidence of Carcinogenic Activity** is demonstrated by studies that are interpreted as showing a chemically related increased incidence of neoplasms (malignant, benign, or combined) in which the strength of the response is less than that required for clear evidence.

- **Equivocal Evidence of Carcinogenic Activity** is demonstrated by studies that are interpreted as showing a marginal increase of neoplasms that may be chemically related.

- **No Evidence of Carcinogenic Activity** is demonstrated by studies that are interpreted as showing no chemically related increases in malignant or benign neoplasms.

- **Inadequate Study of Carcinogenic Activity** is demonstrated by studies that because of major qualitative or quantitative limitations cannot be interpreted as valid for showing either the presence or absence of carcinogenic activity.

When a conclusion statement for a particular experiment is selected, consideration must be given to key factors that would extend the actual boundary of an individual category of evidence. This should allow for incorporation of scientific experience and current understanding of long-term carcinogenesis studies in laboratory animals, especially for those evaluations that may be on the borderline between two adjacent levels. These considerations should include:

- The adequacy of the experimental design and conduct;
- Occurrence of common versus uncommon neoplasia;
- Progression (or lack thereof) from benign to malignant neoplasia as well as from preneoplastic to neoplastic lesions;
- Some benign neoplasms have the capacity to regress but others (of the same morphologic type) progress. At present, it is impossible to identify the difference. Therefore, where progression is known to be a possibility, the most prudent course is to assume that benign neoplasms of those types have the potential to become malignant;
- Combining benign and malignant tumor incidences known or thought to represent stages of progression in the same organ or tissue;
- Latency in tumor induction;
- Multiplicity in site-specific neoplasia;
- Metastases;
- Supporting information from proliferative lesions (hyperplasia) in the same site of neoplasia or in other experiments (same lesion in another sex or species);
- The presence or absence of dose relationships;
- The statistical significance of the observed tumor increase;
- The concurrent control tumor incidence as well as the historical control rate and variability for a specific neoplasm;
- Survival-adjusted analyses and false positive or false negative concerns;
- Structure-activity correlations; and
- In some cases, genetic toxicology.

CONTRIBUTORS

The NTP Technical Report on the Toxicology and Carcinogenesis Studies of 3,3′-Dimethoxybenzidine Dihydrochloride is based on 13-week studies that began in June 1982 and ended in September 1982 and on 21-month studies that began in March 1983 and ended in December 1984 at Hazleton Laboratories America, Inc. (Vienna, VA).

PEER REVIEW PANEL

The members of the Peer Review Panel who evaluated the draft Technical Report on 3,3′-dimethoxybenzidine dihydrochloride on June 27, 1989, are listed below. Panel members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, Panel members have five major responsibilities: (a) to ascertain that all relevant literature data have been adequately cited and interpreted, (b) to determine if the design and conditions of the NTP studies were appropriate, (c) to ensure that the Technical Report presents the experimental results and conclusions fully and clearly, (d) to judge the significance of the experimental results by scientific criteria, and (e) to assess the evaluation of the evidence of carcinogenicity and other observed toxic responses.

SUMMARY OF PEER REVIEW COMMENTS ON THE TOXICOLOGY AND CARCINOGENESIS STUDIES OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

On June 27, 1989, the draft Technical Report on the toxicology and carcinogenesis studies of 3,3'-dimethoxybenzidine dihydrochloride received public review by the National Toxicology Program Board of Scientific Counselors' Technical Reports Review Subcommittee and associated Panel of Experts. The review meeting was held at the National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Dr. D. Morgan, NIEHS, began the discussion by reviewing the experimental design, results, and proposed conclusions (clear evidence of carcinogenic activity for male and female rats). Dr. Morgan explained that the studies were intended to last 24 months but were terminated after 21 months because of the rapidly declining survival of exposed animals due to neoplasia.

Dr. McKnight, a principal reviewer, agreed with the conclusions. She commented that the statistical analysis for skin tumors would be more accurate if based on the time at which a tumor first appeared in each animal, rather than the time at which each animal died with a tumor. (In these studies, this change of analysis would not affect the conclusions.)

Dr. Popp, the second principal reviewer, agreed with the conclusions. He pointed out that, because the chemical had previously been shown to be carcinogenic in experimental animals, information could be added to the rationale for doing the current studies. Dr. Popp noted the observation of foci in the liver of rats after dosing for 9 months, which suggested the chemical might be a hepatocarcinogen, yet there was a relatively weak liver tumor response at 21 months. Dr. Morgan speculated that the early animal deaths may have sufficiently shortened the time available for progression of foci to detectable tumors.

Dr. Gold, the third principal reviewer, agreed with the conclusions. She also requested that the rationale for performing the current studies be mentioned in light of findings from earlier studies. She opined that some of the earlier studies were not adequate by current standards. Dr. Morgan said that the rationale for the studies would be stated earlier in the Introduction and that the inadequacies of the earlier studies would be noted. Dr. Gold asked that the National Institute for Occupational Safety and Health data from the current National Occupational Exposure Survey be appended to indicate the estimated number of U.S. workers exposed to the chemical (page 13). Dr. Scala questioned the accuracy of the exposure estimates. Dr. H. Matthews, NIEHS, proposed that the number of workers exposed to 3,3'-dimethoxybenzidine was likely to be greater that the survey estimates because NTP studies have shown, at least in animals, that dyes derived from benzidine or its congeners were metabolically reduced in vivo almost completely to the parent compound. Dr. Gold also suggested that the results from the study in mice conducted at the National Center for Toxicological Research be included in the Report (page 19).

Dr. Mirer said that another rationale for the NTP studies could be that there is no tumor site concordance between humans and animals. Dr. J. Huff, NIEHS, responded that there were no epidemiology studies on this congener to enable determination of concordance. He added that there is a comparable neoplastic site (urinary bladder) in humans and dogs exposed to the parent chemical, benzidine.

Dr. McKnight moved that the Technical Report on 3,3'-dimethoxybenzidine dihydrochloride be accepted with the revisions discussed and the conclusions as written for male and female rats, clear evidence of carcinogenic activity. Dr. Popp seconded the motion, which was accepted unanimously.

I. INTRODUCTION

3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

CAS No. 20325-40-0

$C_{14}H_{16}N_2O_2 \cdot 2HCl$ Molecular weight 317.2

Synonyms: *o*-dianisidine dihydrochloride; 3,3'-dimethoxy-(1,1-biphenyl)-4,4'-diamine dihydrochloride; 3,3'-dimethoxy-4,4'-diaminobiphenyl dihydrochloride

Use and Production

3,3'-Dimethoxybenzidine dihydrochloride is an off-white powder with a melting point of 274° C. 3,3'-Dimethoxybenzidine is used principally as an intermediate in the production of commercial bisazobiphenyl dyes for coloring textiles, paper, plastic, rubber, and leather (Fishbein, 1981). In the synthesis of the bisazobiphenyl dyes, the amine groups of 3,3'-dimethoxybenzidine are chemically linked with other aromatic amines. A small quantity of 3,3'-dimethoxybenzidine is also used as an intermediate in the production of *o*-dianisidine diisocyanate, which is used in isocyanate-based adhesive systems and as a component of polyurethane elastomers (Woolrich and Rye, 1969; Fishbein, 1981).

3,3'-Dimethoxybenzidine has been produced commercially in the United States for at least 50 years (Fishbein, 1981). 3,3'-Dimethoxybenzidine is synthesized by reduction of *o*-nitroanisole to hydrazoanisole, followed by rearrangement of hydrazoanisole with acid to yield 3,3'-dimethoxybenzidine (IARC, 1974).

Domestic production of 3,3'-dimethoxybenzidine was reduced from 367,000 pounds in 1967 to small quantities in 1978 (USEPA, 1980). No information on more recent production volume is available. Approximately 554,000 pounds of 3,3'-dimethoxybenzidine was imported in 1978 (USEPA, 1980) and 106,000 pounds in 1983 (USITC, 1984). The National Institute for Occupational Safety and Health (NIOSH) reported 33 commercially available (United States) dyes synthesized from 3,3'-dimethoxybenzidine (Boeniger, 1980). Production and importation of 3,3'-dimethoxybenzidine-based dyes were estimated at 1,329,000 pounds (presscake basis) in 1979.

Exposure

Occupational exposure to 3,3'-dimethoxybenzidine may occur during the manufacture of those dyes in which 3,3'-dimethoxybenzidine is an intermediate. Exposure to 3,3'-dimethoxybenzidine may occur by inhalation, ingestion, or skin absorption (Meigs et al., 1951, 1954; El-Hawari et al., 1979). Exposure may also occur indirectly during handling of the finished 3,3'-dimethoxybenzidine-based dyes. Residual amounts of 3,3'-dimethoxybenzidine may be present in the finished dyes due to incomplete dye synthesis or breakdown of the dye after production. As discussed below, there is also evidence to suggest that 3,3'-dimethoxybenzidine-based dyes are metabolized back to the parent compound in vivo, resulting in exposure to 3,3'-dimethoxybenzidine.

Exposure to benzidine, benzidine congeners, and derived dyes has been estimated to include approximately 1,000 workers in dye manufacturing and approximately 10,000 workers in the various application industries (DETO, 1980). Because many of these compounds are found concurrently in the same industry, it is difficult to estimate the number of exposed workers and the extent of exposure to 3,3'-dimethoxybenzidine alone.

Exposure of workers to 3,3'-dimethoxybenzidine may also occur in clinical laboratories (IARC, 1974; Collier, 1974). 3,3'-Dimethoxybenzidine is commonly used for detection of blood and for the quantitation of chlorine in water and of glucose by the glucose oxidase method (Collier, 1974). According to a recent National Occupational Exposure Survey (NIOSH unpublished data), approximately 490 clinical laboratory technologists and technicians are exposed to 3,3'-dimethoxybenzidine.

Nonoccupational exposure to 3,3'-dimethoxybenzidine-based dyes may occur through contact with paper, fabrics, and leather to which these dyes have been applied and through the use of dyes packaged for home use and paints that contain 3,3'-dimethoxybenzidine. No estimates of consumer exposure to 3,3'-dimethoxybenzidine alone were found.

3,3'-Dimethoxybenzidine has been found in samples of commercially produced and imported sneezing powders (Giehl and Salger, 1983; Charles et al., 1984). The commercial material is usually a mixture of black pepper and sawdust; however, in some cases, 3,3'-dimethoxybenzidine or benzidine has been used in place of black pepper. These powders have reportedly caused severe poisoning in children, but the symptoms of 3,3'-dimethoxybenzidine poisoning were not described (Charles et al., 1984).

Disposition and Metabolism

Rodgers et al. (1983) reported that after intravenous administration to male F344 rats, [^{14}C]3,3'-dimethoxybenzidine was rapidly and extensively metabolized; less than 2% of the radiolabel could be recovered unchanged 30 minutes after dosing. Seventy percent of the radiolabel was excreted in the bile within 72 hours, and 50% was located in the intestinal tract after 2 hours. Three days after either oral or intravenous administration, 50% of the radiolabel had been excreted in the feces and 30%-40% excreted in the urine; 45% of the radiolabel remaining in the animal was present in the liver in the form of covalently bound metabolites. Analysis of the pooled urine (days 0-3) demonstrated that more than 90% of the urinary radiolabel was in the form of metabolites. Unmetabolized 3,3'-dimethoxybenzidine accounted for 3%-9% of the urinary radiolabel, and acetyldimethoxybenzidine accounted for 5% or less (Figure 1).

Reductive metabolism of 3,3'-dimethoxybenzidine-based dyes may result in formation of 3,3'-dimethoxybenzidine (Figure 2). Azo reduction can be carried out by enzymes in the liver or by azo reductase associated with intestinal bacterial flora. Highly polar compounds are not well absorbed from the gut, and therefore the water-soluble sulfonated dyes would not be expected to be well absorbed by mammals (Walker, 1970). For this reason, reductive cleavage of the benzidine-congener azo dyes is thought to occur primarily through bacterial action in the gastrointestinal tract (Martin and Kennelly, 1981; Cerniglia et al., 1982; Brown and Dietrich, 1983; Bos et al., 1984, 1986). The less polar metabolites could then be absorbed and further metabolized by the liver.

3,3'-Dimethoxybenzidine-based dyes have been shown to be metabolized to 3,3'-dimethoxybenzidine in dogs, rats, and humans. After exposure of dogs and rats to two 3,3'-dimethoxybenzidine-based dyes, 3,3'-dimethoxybenzidine was detected in the urine of both species at levels that were reportedly greater than the amount contributed by 3,3'-dimethoxybenzidine contamination of the dyes (Lynn et al., 1980). Genin (1977) also detected 3,3'-dimethoxybenzidine in the urine of rats exposed to two 3,3'-dimethoxybenzidine-based dyes. In the same study, 3,3'-dimethoxybenzidine was detected in the urine of three workers who dried and ground two 3,3'-dimethoxybenzidine-based dyes. Boeniger (1980) reported finding 3,3'-dimethoxybenzidine in the urine of a person who worked with 3,3'-dimethoxybenzidine-based dyes but not with 3,3'-dimethoxybenzidine itself. The urinary 3,3'-dimethoxybenzidine may have resulted from metabolism of the dyes or from exposure to dyes contaminated with 3,3'-dimethoxybenzidine.

Genetic Toxicology

3,3'-Dimethoxybenzidine has been extensively studied for induction of gene mutations in *Salmonella typhimurium*. The chemical was mutagenic with exogenous metabolic activation in strains TA98, TA100, and TA1538 (Anderson and Styles, 1978; Martin and Kennelly, 1981;

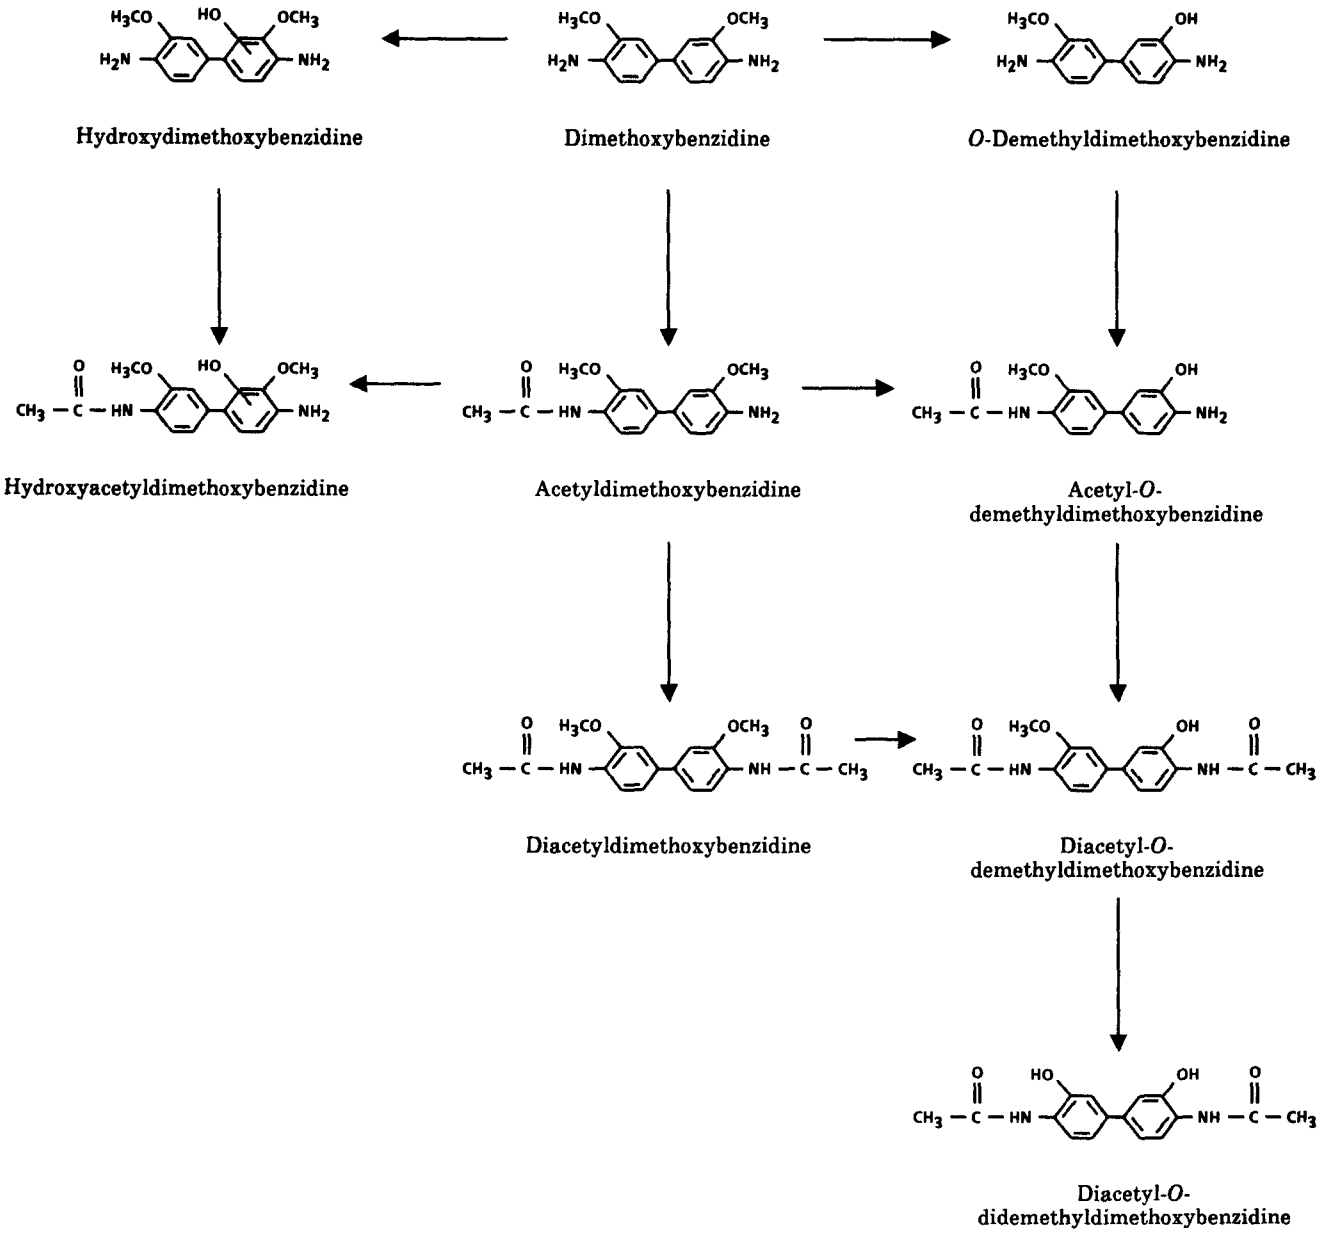

FIGURE 1. PROPOSED METABOLIC PATHWAYS OF 3,3'-DIMETHOXYBENZIDINE
(From Rodgers et al., 1983)

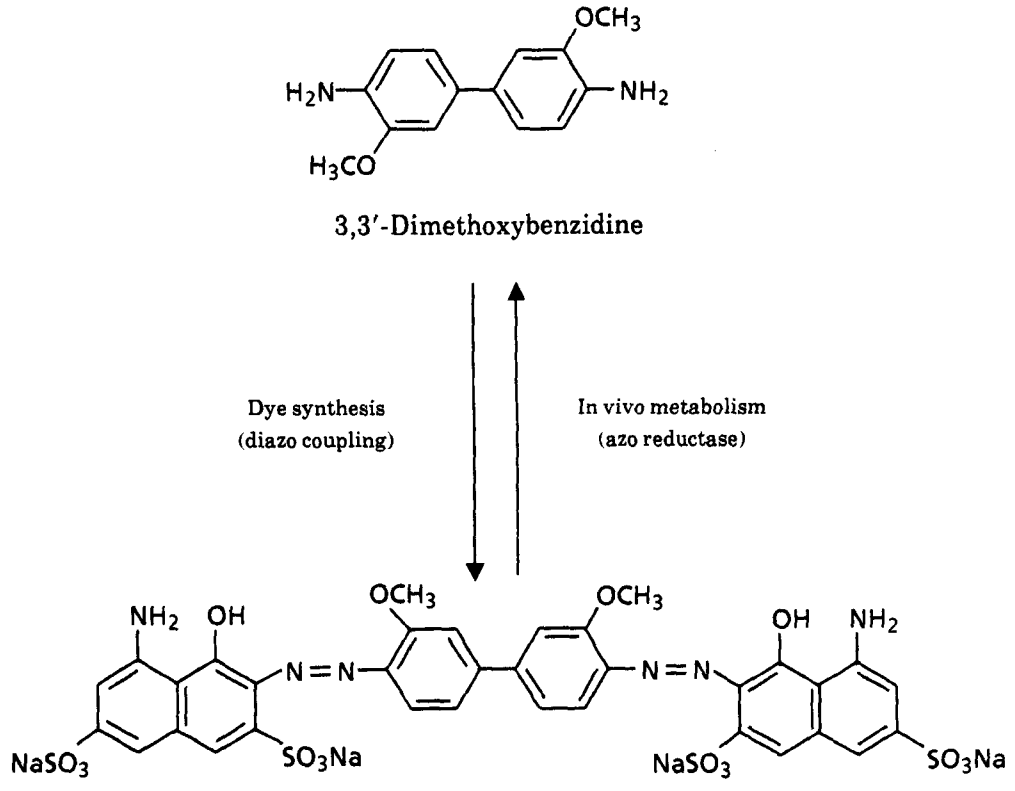

FIGURE 2. FORMATION OF 3,3'-DIMETHOXYBENZIDINE BY REDUCTIVE METABOLISM OF C.I. DIRECT BLUE 15

Probst et al., 1981; Haworth et al., 1983; Rodgers et al., 1983; Reid et al., 1984a,b). Messerly et al. (1987), in a structure-function study of the mutagenic activity of several benzidine derivatives, confirmed the greater activity of 3,3'-dimethoxybenzidine and other substituted aminobiphenyl compounds in *S. typhimurium* TA98 (a strain that mutates via frameshifts) compared with the activity of the chemical in TA100 (a base-substitution strain). The dihydrochloride salt of 3,3'-dimethoxybenzidine also induced gene mutations in *S. typhimurium* TA98 and TA100 (Gregory et al., 1981; Prival et al., 1984; Table H1). Growth inhibition due to induced DNA damage was not observed, however, in *Escherichia coli* treated with 3,3'-dimethoxybenzidine, but this test was performed in the absence of S9 activation (Fluck et al., 1976). Induction of unscheduled DNA synthesis in rat hepatocyte primary cultures treated with 500-1,000 nmol/ml 3,3'-dimethoxybenzidine was reported by Probst et al. (1981). Sister chromatid exchanges were significantly increased in Chinese hamster ovary cells treated with 3,3'-dimethoxybenzidine dihydrochloride with and without S9 metabolic activation (Galloway et al., 1985; Table H2). When originally reported, the results of the chromosomal aberration tests were considered to be negative (Galloway et al., 1985); however, by an updated statistical reanalysis of the chromosomal aberration data (Galloway et al., 1987), the results currently are considered to be weakly positive in the absence of S9 and positive with S9 (Table H3). Negative results were obtained in a *Drosophila melanogaster* sex-linked recessive lethal test in which the chemical was administered by two routes, feeding or injection (Yoon et al., 1985; Table H4).

Mutagenicity data for several metabolites and structural analogs of 3,3'-dimethoxybenzidine are consistent with the positive results in Salmonella and mammalian cell assays seen with 3,3'-dimethoxybenzidine. Benzidine, the parent compound in this series of substituted biphenyls, is positive for induction of gene mutations in *S. typhimurium* TA98, TA100, and TA1538 in the presence of S9 (Ames et al., 1973; Shimizu and Takemura, 1976; Anderson and Styles, 1978; Probst et al., 1981; Baker and Bonin, 1981; Haworth et al., 1983; Reid et al., 1984b) as well as in some strains of *E. coli* with S9 (Venitt and Crofton-Sleigh, 1981; Mohn et al., 1981; Matsushima et al., 1981). Like benzidine, two metabolites of 3,3'-dimethoxybenzidine, *N,N'*diacetyldimethoxybenzidine and *N*-acetyldimethoxybenzidine, were both positive in *S. typhimurium* TA98, TA100, and TA1538 in the presence of S9 activation (Kennelly et al., 1984; Reid et al. 1984b).

Toxicity and Carcinogenicity Studies

In 1980, NIOSH and the Occupational Safety and Health Administration (OSHA) issued a health hazard alert stating that persons working with 3,3'-dimethoxybenzidine-, benzidine-, or 3,3'-dimethylbenzidine-based dyes should be aware of the potential health hazards associated with excess exposure (Boeniger, 1980). In a later report issued to alert workers of the hazards of benzidine-congener dyes, NIOSH stated that workplace exposure to dyes based on 3,3'-dimethoxybenzidine may pose a carcinogenic risk to workers (NIOSH, 1983). These conclusions were based on evidence from animal studies indicating that 3,3'-dimethoxybenzidine is carcinogenic and on preliminary evidence that dyes derived from 3,3'-dimethoxybenzidine may be metabolically converted to the parent compound.

Earlier studies showed that repeated exposure to 3,3'-dimethoxybenzidine results in neoplasms in the gastrointestinal tract, Zymbal gland, skin, and mammary gland of rats and hamsters (Pliss, 1963, 1965; Saffiotti et al., 1967; Hadidian et al., 1968). Although these early studies provided evidence that 3,3'-dimethoxybenzidine is carcinogenic, the use of small numbers of animals, the use of toxic doses, and poor animal survival weakened this evidence. In addition, the doses of 3,3'-dimethoxybenzidine administered in earlier feed studies are questionable, since in the current studies, 3,3'-dimethoxybenzidine was shown to be unstable in rodent feed.

Pliss (1963, 1965) reported on the effects of orally administered 3,3'-dimethoxybenzidine (30 mg, three times per week, via gavage in sunflower oil) in rats. This dose was reduced to 15 mg after 3 weeks because of poor survival. Administration at the lower dose was continued for 13 months. The study was started with 42 rats, and 18 survived through month 14. Two of these 18 animals had neoplasms of the Zymbal gland, and 1 had an ovarian neoplasm. None of the 50 control rats developed neoplasms at the same sites as the exposed rats.

Saffiotti et al. (1967) fed diets containing 1,000 ppm 3,3'-dimethoxybenzidine to Syrian golden hamsters (30 males and 30 females per group) in a lifespan study. A transitional cell carcinoma of the urinary bladder was found in one animal after 144 weeks of exposure. This neoplasm is rare in hamsters and was attributed to 3,3'-dimethoxybenzidine exposure. Sellakumar et al. (1969) conducted a similar study in which a higher dietary concentration of 3,3'-dimethoxybenzidine (10,000 ppm) was administered to hamsters. Forestomach papillomas were detected in 37% of the exposed animals and in only 2% of the controls, but no urinary bladder lesions were detected. This publication is an abstract and does not detail the experimental design or survival data.

Hadidian et al. (1968) administered 3,3'-dimethoxybenzidine by gavage (0.1, 0.3, 1, 3, 10, or 30 mg per animal per day, 5 days per week) to groups of 3 or 14 (10-mg dose only) male and 3 or 15 (10-mg dose only) female F344 rats. The vehicle was a proprietary mixture composed of sodium chloride, sodium carboxymethylcellulose, polysorbate 80, and benzyl alcohol in water. The animals were exposed for 52 weeks and observed for an additional 6 months; necropsies were then performed. Neoplasms occurred as early as day 293, but most were detected at necropsy 18 months after the initial administration of 3,3'-dimethoxybenzidine. A variety of neoplasms were reported, and pooled results for all dosed male and female groups included neoplastic lesions of the urinary bladder (two papillomas), mammary gland (three carcinomas, two fibroadenomas), skin (five carcinomas), intestinal

tract (three carcinomas), and Zymbal gland (eight carcinomas). Incidences of neoplasms were significantly increased over those of the 360 pooled vehicle and untreated control rats.

No epidemiologic data on the occurrence of cancer in workers exposed to 3,3'-dimethoxybenzidine in the absence of other compounds suspected of being carcinogenic were found in the literature. No reports on the carcinogenicity of 3,3'-dimethoxybenzidine-derived dyes in animals or humans were found in the literature.

Toxicity and Carcinogenicity of Related Compounds

Benzidine: 3,3'-Dimethoxybenzidine is a congener of benzidine, a known carcinogen for humans (Scott, 1952; Case et al., 1954; IARC, 1972a; Zavon et al., 1973), rats (Spitz et al., 1950; Griswold et al., 1968), hamsters (Saffiotti et al., 1966), and mice (Bonser et al., 1956; Prokofjeva, 1971; IARC, 1972a; Frith and Dooley, 1976). Benzidine has been shown to produce urinary bladder tumors in as many as 90% of workers who have been exposed for up to 30 years (Scott, 1952). Exposure to benzidine may occur directly or by reductive metabolism of benzidine-based dyes. The carcinogenicity of benzidine has been extensively reviewed (IARC, 1972a, 1982, 1987a; Haley, 1975; USEPA, 1980).

Benzidine exposure has been shown to cause urinary bladder tumors in 1/7 dogs (Spitz et al., 1950); hepatocellular, harderian gland, and lymphoreticular tumors in mice (Bonser et al., 1956; Vesselinovitch et al., 1975; Frith and Dooley, 1976; Littlefield et al., 1983); Zymbal gland, hepatic, and mammary gland carcinomas in rats (Spitz et al., 1950; Griswold et al., 1968); and hepatocellular carcinomas, adenomas, and cholangiomas in hamsters (Saffiotti et al., 1967). In many of the carcinogenicity studies on benzidine, animal survival was poor, primarily because of administration of toxic doses. These studies, however, leave no doubt that benzidine is carcinogenic for laboratory animals.

3,3'-Dimethylbenzidine: 3,3'-Dimethylbenzidine, a methylated congener of benzidine and a structural analog of 3,3'-dimethoxybenzidine, has been shown to be carcinogenic in laboratory animals. In early studies, Spitz et al. (1950) demonstrated the ability of the compound to induce Zymbal gland neoplasms in rats. In a series of experiments, 3,3'-dimethylbenzidine administered subcutaneously to rats was shown to cause neoplasms of the Zymbal gland, small intestine, and mammary gland (Pliss, 1963, 1965; Pliss and Zabezhinsky, 1970). The IARC (1972b) reviewed the literature on 3,3'-dimethylbenzidine and concluded that it was a systemic carcinogen for rats when given subcutaneously.

o-Anisidine: o-Anisidine (2-methoxyaniline) is structurally analogous to one-half the 3,3'-dimethoxybenzidine molecule. o-Anisidine is used in the manufacture of monoazo dyes by diazotization and coupling with other aromatic amines (Noller, 1965). In 103-week studies, o-anisidine hydrochloride was found to be carcinogenic for F344 rats and B6C3F$_1$ mice (NCI, 1978a). Groups of 55 animals of each species and sex received o-anisidine in feed at either 5,000 or 10,000 ppm for rats and 2,500 or 5,000 ppm for mice. Controls consisted of 55 untreated animals of each sex and species. Administration of o-anisidine hydrochloride resulted in transitional cell carcinomas or papillomas of the bladder in each sex of each species, transitional cell carcinomas of the renal pelvis in male rats, and follicular cell neoplasms of the thyroid gland in male rats. Only one control animal had any neoplasms of the urinary system (a transitional cell papilloma of the renal pelvis in a male mouse).

3,3'-Dimethoxybenzidine-4,4'-diisocyanate: 3,3'-Dimethoxybenzidine is a hydrolysis product of 3,3'-dimethoxybenzidine-4,4'-diisocyanate (dianisidine diisocyanate). Although there is presently no known producer of dianisidine diisocyanate, it was produced by one U.S. manufacturer in the 1970's (IARC, 1986). Dianisidine diisocyanate can be used as a component of polyurethane elastomers and in isocyanate-based adhesives (NCI, 1979; IARC, 1986). In 78-week studies, dianisidine diisocyanate was found to be carcinogenic for F344 rats but not for B6C3F$_1$ mice (NCI, 1979). Dianisidine diisocyanate was administered at either of two concentrations to 50 animals of each species and sex. The compound was administered in feed, with the exception of the first 22 weeks of the study in rats when it was administered by gavage. Controls consisted of 20 animals of each sex and species. The doses of dianisidine diisocyanate administered by gavage to rats were 1,500 and 3,000 mg/kg per day, 5 days per week. Dietary

concentrations for rats and mice were 22,000 and 40,000 ppm. Animals were chemically exposed for 78 weeks, followed by an observation period of 26 weeks for rats and 25 weeks for mice. In rats, administration of dianisidine diisocyanate resulted in neoplasms of the skin in males, endometrial stromal polyps in females, and leukemia and malignant lymphomas in each sex. Dianisidine diisocyanate administration was also associated with the development of a combination of squamous cell carcinomas and sebaceous adenocarcinomas of the Zymbal gland and skin of the ear in rats of each sex. There was no evidence of carcinogenicity of dianisidine diisocyanate for B6C3F$_1$ mice.

Study Rationale

Benzidine is known to cause cancer in humans (IARC, 1972a, 1987a), and 3,3'-dimethoxybenzidine, a benzidine congener, is suspected of possessing carcinogenic potential for humans (Fishbein, 1981). Numerous benzidine and benzidine congener-based dyes have been shown to be metabolized to their parent amines in vivo (Rinde and Troll, 1975; Lynn et al., 1980). Consequently, all benzidine-derived and benzidine congener-derived dyes are logical candidates for carcinogenicity evaluation in laboratory animals.

The National Toxicology Program's (NTP's) Benzidine Dye Initiative is a collaborative effort of the National Institute of Environmental Health Sciences, the National Center for Toxicological Research (NCTR), NIOSH, the U.S. Environmental Protection Agency, the Consumer Product Safety Commission, and OSHA, under the aegis of the NTP. The objective of this Initiative was to develop an integrated body of data concerning the metabolism and pharmacokinetics, genetic toxicology, and in vivo carcinogenicity of dyes derived from benzidine, 3,3'-dimethylbenzidine, and 3,3'-dimethoxybenzidine (Table 1). Because studying each of the hundreds of benzidine-based dyes was considered to be impractical, the research program was designed to evaluate representative benzidine congeners and benzidine congener-derived dyes.

3,3'-Dimethoxybenzidine was selected by the collaborating agencies for study in the Initiative to allow comparison of its toxic and carcinogenic effects with those of related chemicals that were studied simultaneously with comparable doses and the same study design. In addition, 3,3'-dimethoxybenzidine was studied to strengthen the evidence for its carcinogenicity. Although results of earlier studies suggested that 3,3'-dimethoxybenzidine was carcinogenic (Pliss, 1963, 1965; Saffiotti et al., 1967; Hadidian et al., 1968), these studies have been criticized because of the use of small groups of animals, the use of toxic doses, poor survival, and the use of parenteral routes of administration (Haley, 1975; DETO, 1980).

(a) G = genetic toxicology; P = pharmacokinetic studies; M = metabolism studies for detection of carcinogens in urine; B = toxicology and carcinogenicity studies.

3,3′-Dimethoxybenzidine dihydrochloride is one of five chemicals being evaluated in the 2-year carcinogenicity studies as part of the Benzidine Dye Initiative. The other chemicals currently being studied are C.I. Direct Blue 15 and C.I. Direct Blue 218 (representative 3,3′-dimethoxybenzidine-based dyes), 3,3′-dimethylbenzidine dihydrochloride (a related benzidine congener), and C.I. Acid Red 114 (a representative 3,3′-dimethylbenzidine-based dye). The oral route of administration was selected for the 3,3′-dimethoxybenzidine dihydrochloride, C.I. Direct Blue 15, 3,3′-dimethylbenzidine dihydrochloride, and C.I. Acid Red 114 studies to maximize the chances of detecting systemic effects associated with chemical administration. These four chemicals were studied with the same study design and with staggered starts over a period of 4 months. Because of the instability of 3,3′-dimethoxybenzidine and 3,3′-dimethylbenzidine in feed, all four chemicals were administered in drinking water.

Long-term studies of 3,3′-dimethoxybenzidine dihydrochloride are being conducted in mice at the NCTR as part of the Benzidine Initiative. Male and female (840 each) BALB/c mice were given 0, 20, 40, 80, 160, 315, or 630 ppm 3,3′-dimethoxybenzidine dihydrochloride in drinking water. Animals were killed after exposure for 13, 26, 39, 52, 78, or 112 weeks, and complete necropsies and histopathologic examinations were performed. 3,3′-Dimethoxybenzidine dihydrochloride was not carcinogenic in BALB/c mice (Schieferstein et al., 1989)

II. MATERIALS AND METHODS

PROCUREMENT AND CHARACTERIZATION OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

A single lot of 3,3'-dimethoxybenzidine dihydrochloride (lot no. 11F-5034) was obtained from Sigma Chemical Company (St. Louis, MO) in two batches. Purity and identity analyses were conducted at Midwest Research Institute (Kansas City, MO) (Appendix G). The study chemical in both batches was identified as 3,3'-dimethoxybenzidine dihydrochloride by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy. Lot no. 11F-5034 was found to be approximately 98% pure, as determined by elemental analysis, Karl Fischer water analysis, potentiometric titration of the two amine groups, thin-layer chromatography, and high-performance liquid chromatography. Comparison of batch no. 1 and batch no. 2 by high-performance liquid chromatography indicated no significant differences between the two batches.

The identity of the chemical at the laboratory was confirmed by infrared spectroscopy. The stability of the study material was monitored by high-performance liquid chromatography and nonaqueous titration of the amine groups. No deterioration of the study material was seen over the course of the studies.

CHARACTERIZATION OF FORMULATED DRINKING WATER MIXTURES

The stability of 3,3'-dimethoxybenzidine dihydrochloride mixed with NIH 07 Rat and Mouse Ration at 200 ppm and stored for 2 weeks at temperatures ranging from −20° C to room temperature was determined. The feed mixtures were extracted and analyzed by gas chromatography using a 3% OV-17 column and flame ionization detection. The formulated diets were found to be unstable under all storage conditions at or above 5° C. Formulated diets stored open to air and light under simulated animal room conditions lost 12.4% or 18.2% of the chemical after 3 or 7 days, respectively. The same feed mixtures stored in the dark in sealed containers lost 1.6%, 8.9%, or 25.7% of the chemical after storage for 2 weeks at −20° C, 5° C, or room temperature.

Because the feed blends of 3,3'-dimethoxybenzidine dihydrochloride were found to be unstable, drinking water was selected as the route of administration for these studies. The 14-day stability of 3,3'-dimethoxybenzidine dihydrochloride in water at 200 ppm (200 µg/ml), stored at room temperature or at 5° C, was determined. The water solutions were diluted with methanol and analyzed by high-performance liquid chromatography with a C_{18} column and ultraviolet detection at 280 nm. The 3,3'-dimethoxybenzidine dihydrochloride/water solutions were found to be stable for at least 14 days when stored in the dark at room temperature or at 5° C. The water solutions were also stable under simulated dosing conditions for at least 48 hours. Drinking water mixtures were prepared two times per week and were used immediately or, for the 21-month studies, stored at room temperature for up to 7 days before being used.

During the 21-month studies, the drinking water mixtures were analyzed at approximately 4-week intervals. For the 3,3'-dimethoxybenzidine dihydrochloride studies, it was estimated that the mixtures were formulated within ±10% of the target concentrations approximately 99% (103/104) of the time throughout the studies (Table G3). Results of periodic referee analysis performed by the analytical chemistry laboratory indicated good agreement with the results from the study laboratory (Table G4).

FOURTEEN-DAY STUDIES

Male and female F344/N rats were obtained from Frederick Cancer Research Facility and were held for 17 days before the studies began. The rats were 7 weeks old when placed on study.

Groups of five rats of each sex received 0, 200, 350, 750, 1,500, or 4,500 ppm 3,3'-dimethoxybenzidine dihydrochloride in drinking water for 14 days.

Animals were housed five per cage. Water and feed were available ad libitum. The rats were observed two times per day and were weighed on days 1, 7 (males) or 4 (females), and 14. A necropsy was performed on all animals. Organ weight to body weight ratios were determined for brain, lung, heart, liver, kidney, right testis, and thymus. Complete histopathologic

examinations were performed on all controls and animals in the 4,500-ppm groups. The spleen, bone marrow (sternum), and thymus in 1,500-ppm males and bone marrow (sternum) in 1,500-ppm females were examined. Further details are presented in Table 2.

THIRTEEN-WEEK STUDIES

Thirteen-week studies were conducted to evaluate the cumulative toxic effects of repeated exposure to 3,3'-dimethoxybenzidine dihydrochloride and to determine the concentrations to be used in the 2-year studies.

Four-week-old male and female F344/N rats were obtained from Frederick Cancer Research Facility, observed for 14 days, distributed to weight classes, and assigned to dose groups according to a table of random numbers. Rats were 6 weeks old when placed on study.

Groups of 10 rats of each sex received 0, 170, 330, 630, 1,250, or 2,500 ppm 3,3'-dimethoxybenzidine dihydrochloride in drinking water ad libitum for 13 weeks. Rats were housed five per cage. Feed was available ad libitum. Further experimental details are summarized in Table 2.

Animals were observed two times per day; moribund animals were killed. Feed consumption was measured one time per week by cage. Water consumption was measured two times per week. Individual animal weights were recorded one time per week.

Blood was collected from the retro-orbital sinus of all animals at the termination of the studies. Hematocrit values, hemoglobin concentrations, erythrocyte counts, leukocyte counts, and differential leukocyte counts were determined with a Coulter Counter Model S-Plus IV. At the end of the 13-week studies, survivors were killed. A necropsy was performed on all animals. The liver, kidney (right), heart, brain, lung, thymus, and testis (right) were weighed at necropsy. An accumulation of lipofuscin was observed in the thyroid gland after rats were exposed to 3,3'-dimethoxybenzidine for 13 weeks, suggesting a possible chemical effect on thyroid gland function. Thyroid gland function was further evaluated by analyzing the remaining serum samples for changes in triiodothyronine (T_3), thyroxin (T_4), and thyrotropin (TSH). These indices of thyroid gland injury were also investigated in the 2-year studies. T_3, T_4, TSH, blood urea nitrogen, creatinine, lactic dehydrogenase, sorbitol dehydrogenase, and alanine aminotransferase were measured in serum taken from the abdominal aorta at necropsy. T_3 and T_4 were analyzed with the Tri-Tab RIA Diagnostic Kit and the Tetra-Tab RIA Diagnostic Kit (Nuclear Medical Laboratories). TSH analysis was performed by the method of Ridgway et al. (1973). Histopathologic examinations were performed. Tissues and groups examined are listed in Table 2.

NINE-MONTH AND TWENTY-ONE-MONTH STUDIES

Study Design

The 21-month study was originally designed for 24 months using an animal allocation recommended by Portier and Hoel (1984). Additionally, at 9 months, 10 rats of each sex in control groups and 10 rats of each sex in the 330-ppm groups were killed, and at 15 months, 10 rats of each sex in each dose group were to be killed. Animals to be used for the 9- and 15-month studies were designated before the studies were started. Because of the large number of early deaths in the chemically exposed groups, the 15-month interim kill was canceled and these animals were added to the core groups, resulting in 60 rats in the control groups, 45 in the 80-ppm groups, 75 in the 170-ppm groups, and 60 in the 330-ppm groups. The liver, right kidney, heart, brain, lung, thymus, and right testis were weighed at necropsy. Hematocrit values, hemoglobin concentrations, erythrocyte counts, leukocyte counts, and differential leukocyte counts were determined. T_3, T_4, TSH, blood urea nitrogen, creatinine, lactic dehydrogenase, sorbitol dehydrogenase, and alanine aminotransferase were measured in serum taken from the abdominal aorta at necropsy. Histopathologic examinations were performed.

Source and Specifications of Animals

The male and female F344/N rats used in these studies were produced under strict barrier conditions at Simonsen Laboratories. Breeding stock for the foundation colony at the production facility originated at the National Institutes of Health Repository. Animals shipped for study were progeny of defined microflora-associated

parents that were transferred from isolators to barrier-maintained rooms. The rats were shipped to the study laboratory at 3-4 weeks of age and were quarantined at the study laboratory for 2 or 3 weeks. Thereafter, a complete necropsy was performed on five animals of each sex to assess their health status. The rodents were placed on study at 6-7 weeks of age. The health of the animals was monitored during the course of the studies according to the protocols of the NTP Sentinel Animal Program (Appendix C).

Animal Maintenance

The rats were housed five per cage. Feed (Appendix E) and water were available ad libitum. Cages were rotated every 2 weeks during the studies.

Clinical Examinations and Pathology

All animals were observed two times per day. Body weights were recorded one time per week for the first 15 weeks of the studies and then at least one time per month thereafter. Mean body weights were calculated for each group. Animals found moribund and those surviving to the end of the studies were humanely killed. A necropsy was performed on all animals including those found dead. In some cases, a particular organ was autolyzed or lost (e.g., intestine or thymus); thus, the number of animals from which particular organs or tissues were examined microscopically varies and is not necessarily equal to the number of animals that were placed on study. During necropsy, all organs and tissues were examined for grossly visible lesions. All major tissues were fixed and preserved in 10% neutral buffered formalin, processed and trimmed, embedded in paraffin, sectioned, and stained with hematoxylin and eosin for microscopic examination. Tissues examined are listed in Table 2.

When the pathology evaluation was completed by the laboratory pathologist and the pathology data entered into the Toxicology Data Management System, the slides, paraffin blocks, and residual formalin-fixed tissues were sent to the NTP Archives. The slides, blocks, and residual wet tissues were audited for accuracy of labeling and animal identification and for thoroughness of tissue trimming. The slides, individual animal necropsy records, and pathology tables were sent to an independent pathology quality assessment laboratory. The individual animal records and pathology tables were compared for accuracy, slides and tissue counts were verified, and histotechnique was evaluated. All tissues with a tumor diagnosis, all potential target tissues, and all tissues from a randomly selected 10% of the animals were re-evaluated microscopically by a quality assessment pathologist. Target tissues were the oral cavity, intestines, liver, preputial or clitoral gland, Zymbal gland, skin, spleen, bone marrow (male) and mammary gland (female). Nonneoplastic lesions were evaluated for accuracy and consistency of diagnosis only in the potential target tissues, in the randomly selected 10% of animals, and in tissues with unusual incidence patterns or trends.

The quality assessment report and slides were submitted to a Pathology Working Group (PWG) Chairperson, who reviewed microscopically all potential target tissues and any other tissues for which there was a disagreement in diagnosis between the laboratory and quality assessment pathologists. Representative examples of liver, intestine, Zymbal gland, preputial/clitoral gland,

skin, mammary gland, and brain neoplasms and examples of disagreements in diagnosis between the laboratory and quality assessment pathologists were shown to the PWG. The PWG included the quality assessment pathologist and other pathologists experienced in rodent toxicology, who examined the tissues without knowledge of dose group or previously rendered diagnoses. When the consensus diagnosis of the PWG differed from that of the laboratory pathologist, the diagnosis was changed to reflect the opinion of the PWG. This procedure has been described, in part, by Maronpot and Boorman (1982) and Boorman et al. (1985). The final pathology data represent a consensus of contractor pathologists and the NTP Pathology Working Group. For subsequent analysis of pathology data, the diagnosed lesions for each tissue type are combined according to the guidelines of McConnell et al. (1986).

Statistical Methods

Survival Analyses: The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals were censored from the survival analyses at the time they were found to be dead from other than natural causes; animals dying from natural causes were not censored. Statistical analyses for a possible dose-related effect on survival used the method of Cox (1972) for testing two groups for equality and Tarone's (1975) life table test for a dose-related trend. When significant survival differences were detected, additional analyses using these procedures were carried out to determine the time point at which significant differences in the survival curves were first detected. All reported P values for the survival analysis are two-sided.

Calculation of Incidence: The incidence of neoplastic or nonneoplastic lesions is given as the ratio of the number of animals bearing such lesions at a specific anatomic site to the number of animals in which that site was examined. In most instances, the denominators include only those animals for which the site was examined histologically. However, when macroscopic examination was required to detect lesions (e.g., in this study, oral cavity) prior to histologic sampling, or when lesions could have appeared at multiple sites (e.g., lymphomas), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Tumor Incidence: In this study, the large numbers of dosed rats that died or were killed in a moribund condition early in the study were considered to be due primarily to skin, preputial gland, clitoral gland, Zymbal gland, and malignant mammary gland tumors. Consequently, for these particular lesions, primary emphasis in the analysis of tumor incidence was given to the life table test (Cox, 1972; Tarone, 1975), a survival-adjusted procedure appropriate for rapidly lethal tumors.

For incidental tumors (i.e., tumors discovered as the result of death from an unrelated cause), one method of analysis used in this study was logistic regression. This method of adjusting for intercurrent mortality is the prevalence analysis of Dinse and Lagakos (1983), further described and illustrated by Dinse and Haseman (1986). However, markedly reduced survival in exposed animals (due largely to increased incidences of lethal tumors) reduced the power of logistic regression to detect carcinogenic effects in some instances. Hence, although the results of logistic regression analysis are given in the appendixes for informational purposes, in the evaluation of incidental tumors, primary emphasis was given to Cochran-Armitage and Fisher exact tests based on the "effective" number of animals, i.e., the number of animals surviving until observation of the first tumor at that tissue site. These survival-adjusted procedures are recommended by Gart et al. (1979).

Tests of significance include pairwise comparisons of each dosed group with controls and a test for an overall dose-response trend. Continuity-corrected tests were used in the analysis of tumor incidence, and reported P values are one-sided. The procedures described above also were used to evaluate selected nonneoplastic lesions. (For further discussion of these statistical methods, see Haseman, 1984.)

Historical Control Data: Although the concurrent control group is always the first and most appropriate control group used for evaluation, there are certain instances in which historical control data can be helpful in the overall assessment of tumor incidence. Although the current studies were terminated at month 21, control

tumor incidences from the NTP historical control data base for 24-month studies (Haseman et al., 1984, 1985) are included for those tumors appearing to show compound-related effects.

Analysis of Continuous Variables: Organ weight to body weight ratios and hematology and serum chemistry data from the 14-day and 13-week studies were analyzed by the nonparametric multiple comparison procedures of Dunn (1964) and Shirley (1977); Jonckheere's test (Jonckheere, 1954) was used to evaluate the significance of dose-response trends and to determine whether Dunn's or Shirley's test was more appropriate for pairwise comparisons. For the 9-month studies (in which a single dose group was compared with the controls), Wilcoxon's rank sum test (Hollander and Wolfe, 1973) was used to evaluate organ weight, hematology, serum chemistry, and urinalysis data.

III. RESULTS: RATS

FOURTEEN-DAY STUDIES

All rats lived to the end of the studies (Table 3). The final mean body weights of rats that received 4,500 ppm were lower than the initial weights. The final mean body weights of rats that received 1,500 ppm were 4% lower than those of controls. Water consumption decreased as the chemical concentration increased and at 4,500 ppm was less than one-fourth that by the controls. The relative liver and kidney weights were increased, but no microscopic changes were seen in these organs (Table F1). The relative thymus weight for females was significantly lower than that for controls receiving 4,500 ppm, and lymphoid depletion of the spleen in males and females and of the thymus in males was observed. Hypocellularity of the bone marrow was seen at 4,500 ppm (in the groups that lost weight).

THIRTEEN-WEEK STUDIES

All rats lived to the end of the studies (Table 4). Final mean body weights of rats receiving 1,250 or 2,500 ppm were 10% or 20% lower than that of the controls for males and 5% or 11% lower for females. Water consumption at 1,250 or 2,500 ppm was about 60% that by the controls for males and about 45% for females. The relative liver and kidney weights for all groups of dosed male rats, the relative liver weights for females receiving 630 ppm and more, and the relative kidney weights for females receiving 330 ppm and more were significantly greater than those for controls (Table 5). Significant increases in the leukocyte and lymphocyte counts were observed for males receiving 2,500 ppm (Table F2). Segmented neutrophil counts were significantly decreased for males receiving 630 ppm or more and for females receiving 2,500 ppm.

(b) Nine animals were weighed.
*P<0.05
**P<0.01

Erythrocyte counts and hematocrit values were significantly decreased by up to 15% in female rats exposed to 630 ppm or more; however, the lack of a concomitant decrease in hemoglobin suggested that these decreases were due to sample hemolysis and were probably not related to chemical exposure. In male rats, a mild increase (<1,000 cells/μl) in total leukocytes was produced by a combination of a mild increase (<1,300/μl) in lymphocytes and a decrease (<400 cells/μl) in neutrophils. None of these changes is biologically relevant. Mild decreases in creatinine (about 20%) were observed in all groups of dosed males and females. These decreases could be produced by loss of muscle mass. Alternatively, decreased concentrations of creatinine can result from substances that interfere with the assay (e.g., bilirubin or hemoglobin).

Compound-related effects seen at 2,500 ppm included mild exacerbation of nephropathy, a condition commonly seen in F344 rats. Nephropathy, characterized by mild tubular regeneration and lymphocytic inflammatory infiltrates, was observed in 10/10 males and 6/10 females. In addition, brown granular pigment was seen in the cytoplasm of the thyroid gland follicular cells of 10/10 males and 10/10 females. The AFIP method for determination of lipofuscin indicated that the pigment was lipofuscin. The mean serum triiodothyronine (T_3) and thyroxin (T_4) concentrations in females receiving 330 ppm or more and the serum T_4 concentrations in males receiving 170 ppm or more were significantly lower than those in controls. The thyrotropin (TSH) concentrations in dosed rats were not significantly different from those in controls (Table F2.)

Dose Selection Rationale: Because of chemical-related exacerbation of nephropathy and decreased water consumption at higher concentrations in short-term studies, drinking water concentrations of 3,3'-dimethoxybenzidine dihydrochloride selected for rats for the 9-month and 2-year (21-month) studies were 80, 170, and 330 ppm.

NINE-MONTH STUDIES

After exposure to 3,3'-dimethoxybenzidine dihydrochloride at 330 ppm for only 9 months, a carcinoma of the preputial gland in one male, focal hyperplasia of the preputial gland in one male, a carcinoma of the clitoral gland in one female, and carcinomas of the Zymbal gland in two males and focal hyperplasia of the Zymbal gland in two males and two females were detected. None of these lesions was observed in control rats. Low dose and mid dose animals were not examined. Other compound-related effects included basophilic and/or eosinophilic foci of altered cells of the liver in 8/10 males and 5/10 females.

The relative kidney and liver weights for males and females receiving 330 ppm were significantly greater than those for controls (Table 6). Significant decreases were seen for T_3 and T_4 concentrations in both male and female rats receiving 330 ppm (Table F3). Decreases in hemoglobin, erythrocyte counts, hematocrit, and mean corpuscular hemoglobin concentrations were observed in exposed rats and were indicative of mild anemia in male rats only. Decreases in lactic dehydrogenase and alanine aminotransferase activity in the 330-ppm groups are not indicative of hepatocellular damage. Urinalysis revealed no evidence of renal damage; there was no apparent effect on the ability to concentrate urine.

TWENTY-ONE-MONTH STUDIES

Body Weights, Water Consumption, and Clinical Signs

Mean body weights of high dose male rats were within 6% of those of the controls until week 69 and were 11%-22% lower thereafter; mean body weights of mid dose male rats were within 5% of those of the controls until week 69 and were 6%-14% lower thereafter (Table 7 and Figure 3). Mean body weights of high dose female rats were 9%-11% lower than those of controls after week 53; mean body weights of mid dose female rats were 7%-17% lower than those of controls after week 53. Body weight decreases of 22% for high dose males and 17% for mid dose females occurred in the last week of the studies, and calculations of relative body weights were based on only a few surviving animals. The average daily water consumption per rat by low, mid, and high dose rats was 94%, 97%, and 83% that by controls for males and 99%, 97%, and 78% for females (Tables D1 and D2). The average amount of 3,3'-dimethoxybenzidine dihydrochloride consumed per day was approximately 6, 12, or 21 mg/kg for low, mid, or high dose male rats and 7, 14, or 23 mg/kg for low, mid, or high dose female rats. Clinical signs noted during the studies were limited to increased incidences of tissue masses on the head, over the dorsum, and in the genital area in dosed groups.

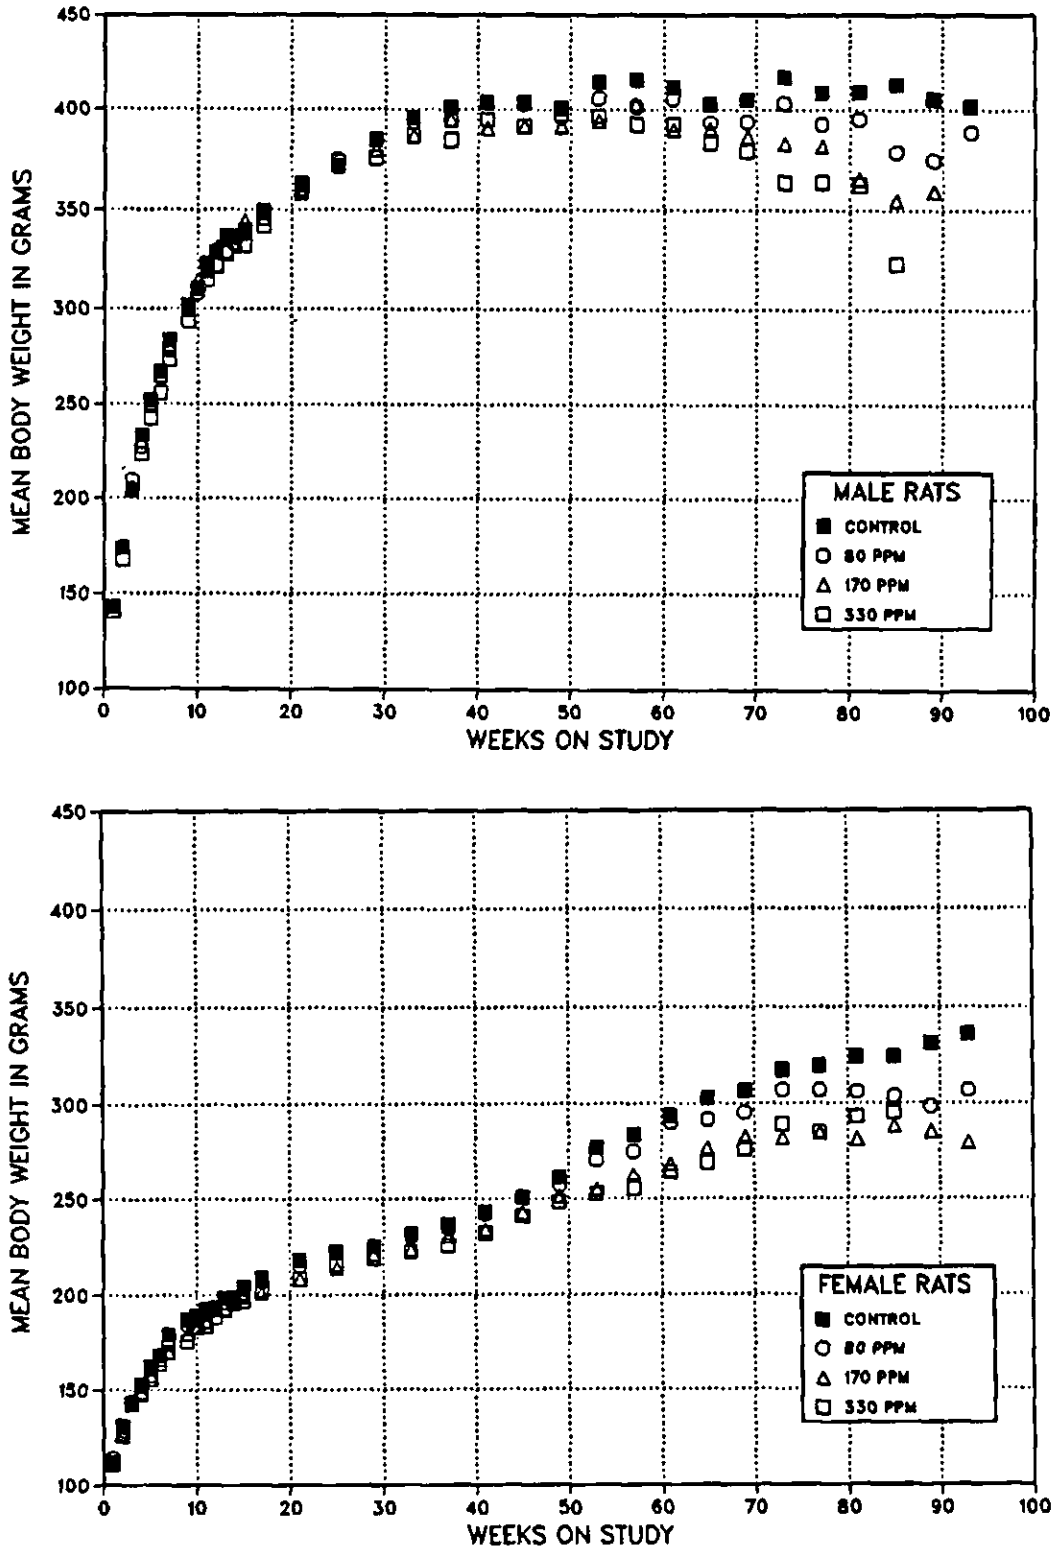

FIGURE 3. GROWTH CURVES FOR RATS GIVEN DRINKING WATER CONTAINING 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE FOR TWENTY-ONE MONTHS

Survival

Estimates of the probabilities of survival for male and female rats given drinking water containing 3,3'-dimethoxybenzidine dihydrochloride at the concentrations used in these studies and for controls are shown in Table 8 and in the Kaplan and Meier curves in Figure 4. The survival of dosed rats was significantly lower than that of controls after day 552 (low dose), 420 (mid dose), or 401 (high dose) for males and day 483 (low dose), 309 (mid dose), or 304 (high dose) for females.

Pathology and Statistical Analyses of Results

This section describes the statistically significant or biologically noteworthy changes in the incidences of rats with neoplastic or nonneoplastic lesions of the liver, large intestine, small intestine, Zymbal gland, preputial gland, clitoral gland, oral cavity, skin, mammary gland, brain, uterus, mesothelium, spleen, mesenteric lymph nodes, heart, lung, and bone marrow.

Summaries of the incidences of neoplasms and nonneoplastic lesions, individual animal tumor diagnoses, statistical analyses of primary tumors that occurred with an incidence of at least 5% in at least one animal group, and historical control incidences for the neoplasms mentioned in this section are presented in Appendixes A and B for male and female rats, respectively.

Liver: The administration of 3,3'-dimethoxybenzidine dihydrochloride in drinking water to

(b) The result of the life table trend test is in the control column, and the results of the life table pairwise comparisons with the controls are in the dosed columns.

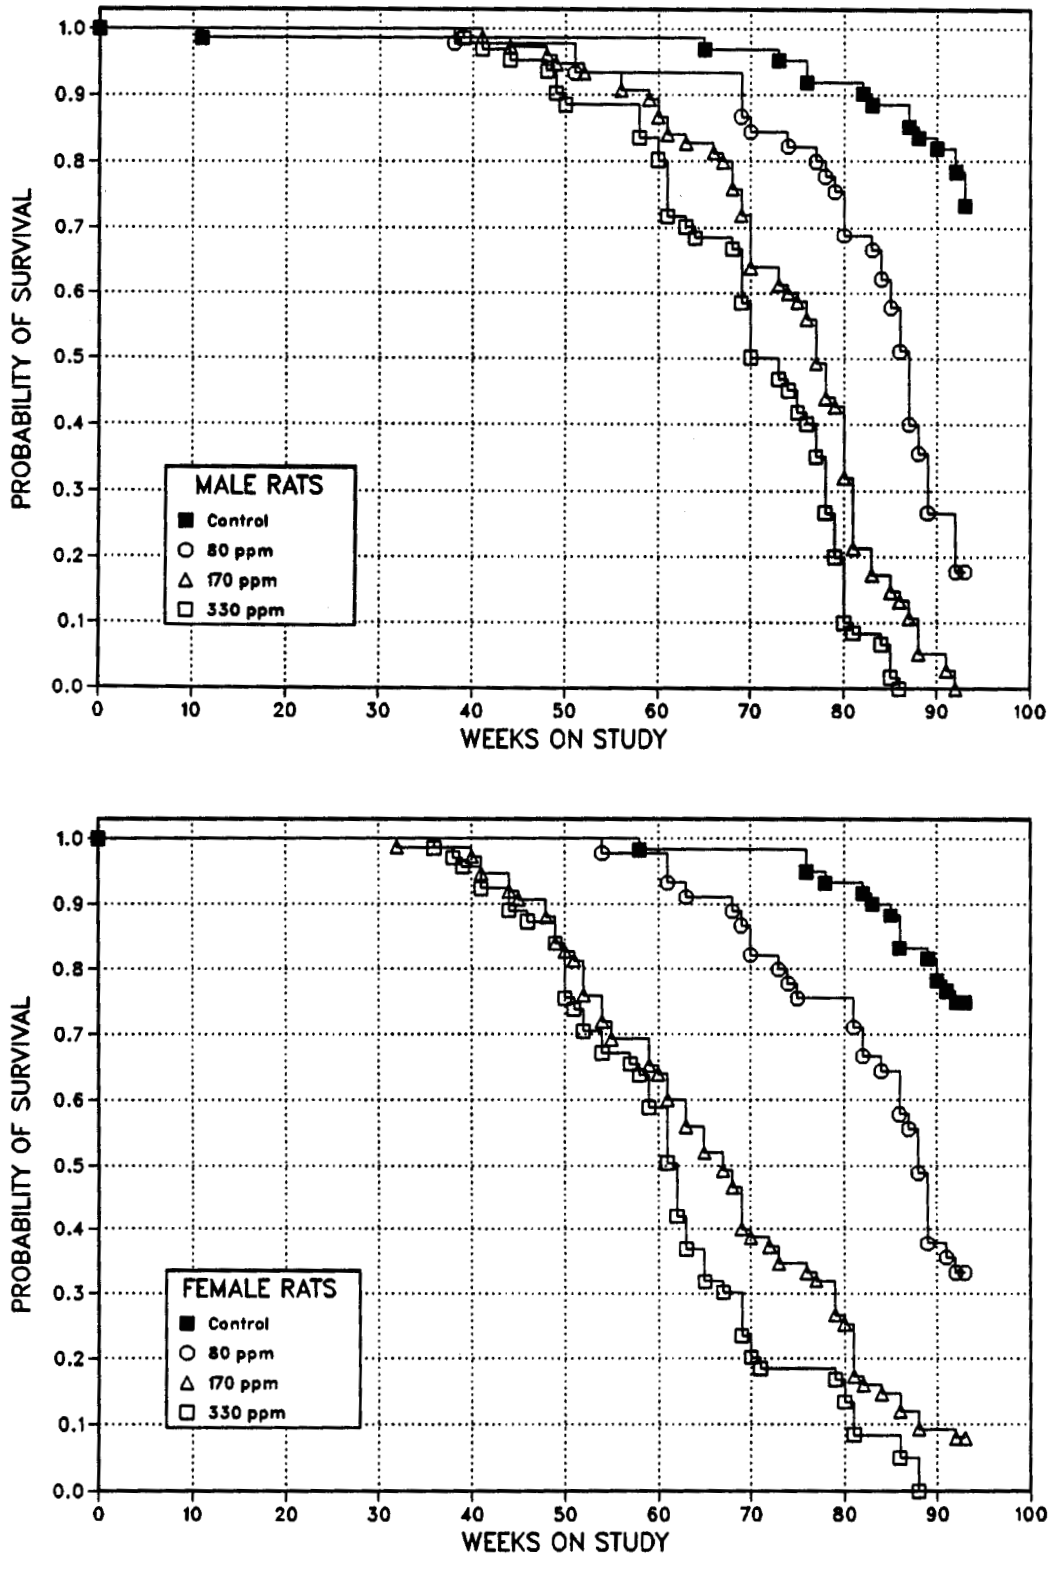

FIGURE 4. KAPLAN-MEIER SURVIVAL CURVES FOR RATS GIVEN DRINKING WATER CONTAINING 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE FOR TWENTY-ONE MONTHS

male and female rats caused a variety of degenerative and proliferative lesions in the liver (Table 9); the lesions were generally more severe and the incidences were greater in dosed males than in females. The degenerative lesions consisted of clusters of hepatocytes containing cytoplasmic vacuoles (presumably lipid droplets), generalized centrilobular hepatocellular degeneration, randomly distributed single or multiple foci of necrosis, and foci of multilocular cysts containing granular eosinophilic material or erythrocytes (cystic degeneration or spongiosis hepatis). Hepatocellular regeneration, characterized by poorly circumscribed foci of enlarged cells with deeply staining eosinophilic cytoplasm, occurred in livers with the more severe degenerative lesions.

The incidences of clear cell foci were marginally increased in high dose male rats and dosed female rats. Eosinophilic foci were increased in both dosed male and female rats. Clear cell foci consisted of poorly circumscribed clusters of hepatocytes with pale cytoplasm, whereas eosinophilic foci consisted of cells with eosinophilic cytoplasm. These foci were generally smaller than a hepatic lobule and showed little or no compression of the surrounding parenchyma; the hepatic plates in the foci merged imperceptibly with the normal plates. Neoplastic nodules in males and neoplastic nodules or hepatocellular carcinomas (combined) in males and females occurred with significant positive trends; the incidences in mid and high dose males were significantly greater than that in controls (Table 10). Neoplastic nodules were expansile lesions that were generally larger than a hepatic lobule and compressed the surrounding tissue; the hepatic plates within the neoplastic nodule were not arranged in a normal lobular pattern. The hepatocytes showed altered staining properties and slight nuclear pleomorphism and atypia. The hepatocellular carcinomas were larger masses consisting of hepatocytes in solid clusters or trabeculae several layers thick without a lobular pattern; the hepatocytes generally showed greater cellular atypia and pleomorphism than those within the neoplastic nodules.

Large Intestine (Colon, Cecum, or Rectum): Adenomatous polyps or adenocarcinomas (combined) in male and female rats occurred with significant positive trends; the incidences in mid and high dose males and high dose females were significantly greater than those in controls (Table 11).

(a) For a complete explanation of the entries in this table, see Table A3 (footnotes); the statistical analyses used are discussed in Section II (Statistical Methods).
(b) Number of tumor-bearing animals/effective number of animals, i.e., number of animals alive at the first occurrence of tumors in any of the four groups
(c) Based on effective rates
(d) No P value is reported because no tumors were observed in the 80-ppm and control groups.
(e) Historical incidence at study laboratory: 0/96; historical incidence in NTP studies (mean ± SD): 2/1,541 (0.1% ± 0.5%)
(f) Historical incidence at study laboratory: 0/88; historical incidence in NTP studies: 0/1,601

Adenomatous polyps were exophytic, polypoid masses that protruded into the intestinal lumen. These consisted of glandular structures lined by a single layer of columnar epithelial cells with round nuclei and moderately abundant basophilic cytoplasm. These cells were generally well differentiated, but mucous cells were not present. The adenocarcinomas were similar exophytic masses that showed invasion of the intestinal submucosa. The glandular structures composing the adenocarcinomas were generally more irregular, particularly at the site of invasion, and the epithelial cells were less well differentiated with some atypia.

Small Intestine: The incidences of adenocarcinomas in dosed males were significantly greater than that in controls (Table 12). Adenocarcinomas were seen in 0/60 control, 1/45 low dose, 1/75 mid dose, and 2/60 high dose female rats. The adenocarcinomas invaded the intestinal wall and consisted of glandular structures lined by moderately well to poorly differentiated columnar epithelium. Several of the neoplasms contained mucus-secreting cells forming large dilated spaces filled with mucus (cystic mucinous adenocarcinomas).

Zymbal Gland: The Zymbal glands are specialized sebaceous glands anterior and ventral to the external orifices of the ears. The incidences of adenomas, carcinomas, and adenomas or carcinomas (combined) were significantly greater in the dosed groups than in the control groups (Table 13). Some dosed rats had bilateral neoplasms of the Zymbal gland.

Hyperplasia, adenomas, and carcinomas are part of a morphologic continuum. Hyperplasia was a focal lesion of the glandular epithelium characterized by enlarged cells that distorted the normal acinar arrangement. Adenomas were circumscribed masses consisting of poorly formed acini surrounding ductlike structures lined by squamous epithelium. Sebaceous cell differentiation was evident in the neoplastic acini. Carcinomas were generally larger and invaded adjacent soft tissues. The neoplastic cells demonstrated heterogeneous growth patterns with irregular, poorly formed acinar structures, solid masses, and cords with scattered ductlike structures filled with secretory material and cellular debris. The neoplasms exhibited predominantly sebaceous or squamous differentiation, but some neoplasms had prominent components of each.

(b) Number of tumor-bearing animals/effective number of animals, i.e., number of animals alive at the first occurrence of tumors in any of the four groups
(c) Based on effective rates
(d) Historical incidence at study laboratory (mean): 1/100 (1%); historical incidence in NTP studies (mean ± SD): 19/1,596 (1% ± 2%)
(e) Historical incidence at study laboratory (mean): 1/100 (1%); historical incidence in NTP studies (mean ± SD): 14/1,643 (0.9% ± 2%)
*P<0.05 vs. controls by Fisher exact test
**P<0.01 vs. controls by Fisher exact test

Preputial or Clitoral Gland: The preputial glands of the male rat are modified sebaceous glands bilateral and adjacent to the penis. The clitoral glands of the female are homologous organs located near the base of the clitoris. Ductular ectasia and glandular hyperplasia occurred at increased incidences in dosed male rats but not in the clitoral gland of female rats (Tables 14 and 15). The incidences of carcinomas and adenomas or carcinomas (combined) of the preputial gland in males occurred with significant positive trends; the incidences in the mid and high dose groups were significantly greater than those in the controls. In female rats, the incidences of adenomas, carcinomas, and adenomas or carcinomas (combined) of the clitoral gland were significantly greater in almost all dosed groups than in controls. Bilateral neoplasms of the preputial and clitoral glands occurred in dosed groups of rats.

Hyperplasia, adenomas, and carcinomas of the preputial and clitoral glands are part of a morphologic continuum. Hyperplasia was characterized by clusters of acini consisting of enlarged cells with prominent nuclei. There was some distortion of the acinar arrangement of the cells. Adenomas were circumscribed, expansile lesions exhibiting loss of normal acinar organization. The neoplastic cells were well differentiated and arranged in solid clusters with scattered ductlike structures containing debris. Carcinomas were poorly circumscribed masses with irregular boundaries, often accompanied by inflammation in the surrounding tissue. Overt invasion of the adjacent soft tissue similar to that seen with Zymbal gland carcinomas was generally not observed. The carcinomas exhibited greater heterogeneity of growth pattern and greater cellular pleomorphism and atypia than adenomas.

(a) For a complete explanation of the entries in this table, see Table B3 (footnotes); the statistical analyses used are discussed in Section II (Statistical Methods).
(b) Number of tumor-bearing animals/effective number of animals, i.e., number of animals alive at the first occurrence of tumors in any of the four groups
(c) Based on effective rates
(d) Historical incidence at study laboratory (mean): 8/100 (8%); historical incidence in NTP studies (mean ± SD): 115/1,643 (7% ± 5%)
*P<0.05 vs. controls by Fisher exact test

Oral Cavity (Palate or Tongue): Squamous papillomas and squamous papillomas or squamous cell carcinomas (combined) of the palate or tongue in males occurred with significant positive trends; the incidences in dosed males were significantly greater than those in controls (Table 16). A few squamous cell papillomas occurred in each of the female dosed and control groups, but squamous cell carcinomas occurred only in the mid and high dose groups. The papillomas consisted of branching papillae arising from the mucosal epithelium and extending into the oral cavity. The papillae had a thickened stratified squamous epithelium overlying a thin core of connective tissue. The squamous cell carcinomas often had exophytic papillary structures similar to the papillomas but showed invasion of the underlying submucosa by cords and clusters of neoplastic squamous epithelium.

Skin: A spectrum of epithelial neoplasms of the skin occurred at markedly increased incidences, primarily in male rats given 3,3'-dimethoxybenzidine dihydrochloride (Tables 17 and 18). The incidences of basal cell adenomas, basal cell carcinomas, squamous cell papillomas, and squamous cell carcinomas in males occurred with significant positive trends; except for basal cell carcinomas in low dose males, the incidences in the dosed groups were significantly greater than those in the controls. Small numbers of sebaceous gland adenomas or carcinomas (combined) occurred in dosed male rats. The incidences of keratoacanthomas were significantly increased in low dose male rats and increased ($P = 0.053$) in mid dose male rats.

Small numbers of basal cell adenomas occurred in dosed groups of female rats but not in controls. A basal cell carcinoma was observed in a single low dose female. The incidence of basal cell adenomas or carcinomas (combined) in low dose female rats was significantly greater than that in controls. Squamous cell papillomas were observed in three mid dose female rats.

The basal cell neoplasms consisted of small basophilic cells arranged in branching cords, solid clusters, or nodules with central cavities. Some exhibited features of hair follicles, whereas others showed sebaceous differentiation. Those with predominantly sebaceous differentiation were diagnosed as sebaceous gland adenomas. The basal cell adenomas were circumscribed masses without local invasion, whereas the carcinomas exhibited cellular anaplasia, necrosis, and/or local invasion. The squamous cell papillomas were typical exophytic growths consisting of branching papillae of stratified squamous epithelium, and the squamous cell carcinomas were composed of cords of well to poorly differentiated squamous epithelium that infiltrated the underlying dermis and subcutaneous tissue.

Mammary Gland: Adenocarcinomas in female rats occurred with a significant positive trend; the incidences in the mid and high dose groups were significantly greater than that in the controls (Table 19). The incidence of adenocarcinomas in high dose female rats was four times the highest observed historical incidence in untreated control female F344/N rats. The incidences of fibroadenomas in dosed females were lower than that in controls, probably because of the reduced survival in the dosed groups.

Brain: Malignant astrocytomas were seen in small numbers of dosed, but not control, rats (Table 20). The historical incidence of astrocytomas in untreated control male F344/N rats is 10/1,590 (0.6%) and in female F344/N rats is 15/1,628 (0.9%).

Uterus: Adenomas or carcinomas (combined) of the uterus or cervix were observed in dosed, but not in control, female rats (Table 21). The incidence of adenomas or carcinomas (combined) in low dose female rats was significantly greater than that in controls.

Mesothelium: Mesotheliomas were marginally increased in male rats (Table 22); the historical incidence of mesotheliomas in untreated control male F344/N rats is 47/1,596 (3%), and the highest observed incidence is 5/50.

(d) Based on effective rates

Spleen: Hematopoietic cell proliferation was observed at increased incidences in dosed rats (male: control, 3/60; low dose, 13/42; mid dose, 43/74; high dose, 38/59; female: 3/60; 22/44; 50/75; 47/60).

Mesenteric Lymph Nodes: Reticulum cell hyperplasia was observed at increased incidences in dosed rats (male: control, 0/59; low dose, 3/42; mid dose, 6/73; high dose, 6/56; female: 2/60; 3/44; 18/75; 18/58).

Heart: Thrombi in the atrium were observed at increased incidences in dosed male rats (male: control, 3/60; low dose, 15/44; mid dose, 27/75; high dose, 23/60; female: 0/60; 1/45; 0/75; 1/60). The increased incidences of atrial thrombosis observed in the heart of exposed males may have been related to compound-caused morbidity, which led to impaired circulation and sludging of blood in the atrial chambers. This effect was not observed in exposed female rats, although there was a similar degree of morbidity.

Lung: Histiocytic cellular infiltration was observed at increased incidences in dosed rats (male: control, 0/60; low dose, 3/44; mid dose, 10/75; high dose, 6/60; female: 0/60; 3/45; 4/75; 18/60).

Bone Marrow: Hyperplasia of myeloid cells was observed at increased incidences in dosed rats (male: control, 2/60; low dose, 3/43; mid dose, 14/74; high dose, 7/60; female: 5/60; 8/45; 9/75; 14/60).

3,3'-Dimethoxybenzidine was tested for induction of gene mutations in *Salmonella typhimurium* strains TA98, TA100, TA1535, and TA1537 in each of three laboratories (Haworth et al., 1983; Table H1). In all laboratories, a response ranging from weakly positive to positive was observed with strain TA100 in trials conducted in the presence of Aroclor 1254-induced male Sprague Dawley rat or Syrian hamster liver S9; likewise, positive results were reported for strain TA98 with S9 in all three laboratories, and one laboratory also observed a significant response in TA98 without S9. A weakly positive response was reported by one of the test laboratories with TA1535 in the presence of induced hamster S9. In cytogenetic tests with Chinese hamster ovary cells conducted in two laboratories, sister chromatid exchanges (SCEs) were induced by 3,3'-dimethoxybenzidine both with and without Aroclor 1254-induced male Sprague Dawley rat liver S9; in one of these two laboratories, the positive responses observed in the SCE trials without S9 occurred under conditions of delayed harvest (3-5 hours additional culture time), but the positive results reported by the second laboratory in the SCE test were observed at lower doses of the study chemical which did not affect cell cycle time (Galloway et al., 1985; Table H2). Results of the chromosomal aberration test were reported to be negative (Galloway et al., 1985); however, recent statistical reanalysis (Galloway et al., 1987) of the chromosomal aberration data has resulted in a change in the call from negative to weakly positive without S9 (Litton Bionetics study) and positive with S9 (Columbia University study) (Table H3). 3,3'-Dimethoxybenzidine was negative for induction of sex-linked recessive lethal mutations in adult male *Drosophila melanogaster* exposed to the chemical by feeding (100 ppm) or injection (200 ppm) (Yoon et al., 1985; Table H4). The methods and results are presented in Appendix H.

IV. DISCUSSION AND CONCLUSIONS

Consumption of drinking water containing 3,3'-dimethoxybenzidine dihydrochloride led to highly significant incidences of neoplasms at a variety of sites and to mild toxicity in several organs. Unusual neoplasm sites in 3,3'-dimethoxybenzidine-exposed rats include the skin, Zymbal gland, preputial and clitoral glands, intestine, and oral mucosa. Most genotoxic carcinogens are associated with unusual tumor sites, and the short latency and multiple sites of these tumors are most characteristic of potent genotoxic carcinogens, such as benzidine dyes (NCI, 1978b), benzene (NTP, 1986), 1,3-butadiene (NTP, 1984), and glycidol (NTP, 1990). 3,3'-Dimethoxybenzidine and related aminobiphenyls are mutagenic. 3,3'-Dimethoxybenzidine requires S9 for mutagenic activation in the Salmonella assay, indicating that the chemical is metabolized to a mutagenic species, most likely through *N*-hydroxylation.

Fourteen-Day and Thirteen-Week Studies

In the 14-day and 13-week studies, male and female rats were exposed to 3,3'-dimethoxybenzidine dihydrochloride in drinking water at concentrations ranging from 170 to 4,500 ppm. Animal survival was unaffected, and few toxic effects were observed. Water consumption was decreased with increasing 3,3'-dimethoxybenzidine dihydrochloride concentration in both studies. In the 13-week studies, mean body weight gains were decreased in the two top dose groups. Compound-related effects seen in the top dose groups of male and female rats included increases in relative liver and kidney weights, nephropathy, and lipofuscin accumulation in the thyroid gland.

Dose-related decreases in serum triiodothyronine (T_3) and thyroxin (T_4) without a change in thyrotropin (TSH) are not consistent with a toxic effect on the thyroid gland; this effect was probably due to a change in the amount or binding capacity of the protein carrier for these hormones rather than to a direct effect on the thyroid gland. 3,3'-Dimethoxybenzidine is similar in structure to T_3 and T_4, suggesting that the dose-related decreases in serum T_3 and T_4 may be due to competition with 3,3'-dimethoxybenzidine for the carrier protein.

Based on the chemical-induced nephropathy and on reductions in water consumption and body weight gain observed in the 13-week studies, doses for the long-term studies in male and female rats were 0 or 330 ppm 3,3'-dimethoxybenzidine dihydrochloride administered in drinking water for 9 months and 0, 80, 170, or 330 ppm for 21 months.

Nine-Month Studies

Carcinomas of the preputial, clitoral, and Zymbal glands were observed after chemical exposure for only 9 months. Basophilic and/or eosinophilic foci in the liver and hyperplasia of the preputial and Zymbal glands were also detected in exposed rats. These lesions were not observed in control rats. The short latency of these lesions is unusual and indicative of the carcinogenic potency of 3,3'-dimethoxybenzidine dihydrochloride.

In the 9-month studies, hematologic effects were indicative of a mild anemia in male rats. Serum enzyme changes were slight and were not considered indicative of liver injury. Serum T_3 and T_4 were decreased, with no change in TSH, and as in the 13-week studies, these changes were not considered to be a direct effect on the thyroid gland.

Twenty-One-Month Studies

3,3'-Dimethoxybenzidine dihydrochloride studies were terminated at month 21 because of reduced survival in the dosed groups (see Table 8 and Figure 4). The reduced survival of dosed rats first became noticeable in males during months 14-15 and in females during month 11. For humane reasons, animals with large visible masses or those in a moribund condition, usually due to internal neoplasms, were killed rather than allowed to suffer; this program may have influenced the overall survival profile. Mean body weights of high dose male and female rats were 4%-22% lower than those of controls during the second year.

Nonneoplastic Lesions

Increased hematopoietic cell proliferation in the liver and spleen, coupled with bone marrow hyperplasia in exposed groups, are probably related to inflammation and necrosis associated with neoplasms.

3,3'-Dimethoxybenzidine dihydrochloride appeared to stimulate the reticuloendothelial system. This effect was manifested as reticulum cell hyperplasia of the mesenteric lymph nodes. Although this effect may be compound related, it is probably a nonspecific reaction.

Neoplastic Lesions

There was a highly significant association between the consumption of 3,3'-dimethoxybenzidine dihydrochloride and the development of Zymbal gland adenomas and/or carcinomas in dosed male and female rats. With the exception of a carcinoma in one control female (first observed during week 58), Zymbal gland neoplasms were not observed in control groups. Carcinomas were observed at necropsy in exposed males and females as early as week 38. Neoplasms develop at this site infrequently (1%) in historical control rats (Tables A4d and B4d) and usually only late in life (Solleveld et al., 1984). Benzidine, the parent compound of 3,3'-dimethoxybenzidine, also causes Zymbal gland tumors in rats, and it is a known urinary bladder carcinogen in humans (IARC, 1982, 1987a).

3,3'-Dimethoxybenzidine dihydrochloride had a profound effect on the preputial and clitoral glands in exposed male and female rats, giving rise to a high incidence of carcinomas and/or adenomas. The incidences of preputial or clitoral gland neoplasms in high dose male and female rats were 7 and 10 times higher, respectively, than in untreated historical control F344/N rats. In exposed rats, carcinomas were confirmed histologically at necropsy as early as week 32 (females) and week 39 (males), whereas in controls, carcinomas were not observed until week 87 in males or at the end of the study at month 21 in females. Potential precursor lesions (hyperplasia) occurred in small numbers of exposed animals, possibly because most such lesions had already progressed to neoplasms.

Of 350 chemicals evaluated for carcinogenicity in rats and mice by the National Cancer Institute/National Toxicology Program (NCI/NTP), only 12 were associated with skin neoplasms; 11 of these 12 chemicals were administered orally or by inhalation. In the current study, 72% of male rats administered 3,3'-dimethoxybenzidine dihydrochloride in drinking water were found to have basal cell and/or sebaceous gland neoplasms of the skin, compared with only 3% of controls. In exposed male rats, basal cell neoplasms occurred as early as week 50; squamous cell neoplasms occurred as early as week 61. The basal cell neoplasms often showed differentiation to structures associated with sebaceous glands or hair follicles. Epithelial skin neoplasms were observed at low incidences in exposed female rats; however, those detected were of the same morphologic type as those observed in males and were considered to be related to 3,3'-dimethoxybenzidine dihydrochloride consumption.

Few substances induce epithelial neoplasms of the skin unless they are applied directly. Although 3,3'-dimethoxybenzidine dihydrochloride was administered in drinking water, exposure of skin during grooming was likely. The possibility that skin neoplasms resulted from direct exposure of the skin to 3,3'-dimethoxybenzidine dihydrochloride or its metabolites in saliva was considered. However, these neoplasms were more likely a result of systemic exposure to reactive 3,3'-dimethoxybenzidine metabolites, because most aromatic amines require metabolic activation to have carcinogenic activity (Miller and Miller, 1974, 1977) and because many skin neoplasms were present on the backs of the animals, where grooming is minimal. No reports on the carcinogenicity of 3,3'-dimethoxybenzidine after dermal application were found.

3,3'-Dimethoxybenzidine dihydrochloride exposure led to development of neoplasms of the small and large intestine in male rats. Chemically induced neoplasms of the intestine are uncommon in rats; of 350 chemicals studied by the NCI/NTP, only 7--tribromomethane (NTP, 1989), bromodichloromethane (NTP, 1987), captan, (NCI, 1977a), phenazopyridine hydrochloride (NCI, 1978c), proflavin hydrochloride (NCI, 1977b), chrysotile asbestos (NTP, 1985), and Aroclor® 1254 (NCI, 1978d)--were associated with adenocarcinomas, adenomatous polyps, or intestinal carcinomas in rats.

In the current studies, neoplasms were principally cystic mucinous adenocarcinomas of the small intestine and adenomatous polyps and adenocarcinomas of the large intestine. Polyps in the colon were first observed at week 48, whereas adenocarcinomas in the small intestine first occurred after 39 weeks of chemical

exposure. Adenocarcinomas in the large intestine were also observed in the low, mid, and high dose groups of exposed female rats; although not as numerous as in males, these neoplasms were considered to be related to 3,3'-dimethoxybenzidine dihydrochloride exposure because no adenocarcinomas or adenomatous polyps of the large intestine have been observed in 1,601 untreated historical control female F344/N rats.

Squamous cell neoplasms that occurred on the tongue and palate of exposed male rats were strongly associated with exposure to 3,3'-dimethoxybenzidine dihydrochloride. Taken collectively, the observed number of squamous cell papillomas and carcinomas of the oral cavity (16% of dosed animals) represents a large increase in the incidence of relatively rare neoplasms (0.4% in untreated control male F344/N rats). Squamous cell neoplasms of the oral cavity were also detected in dosed female rats, although at lower incidences, but the incidences still markedly exceeded the historical incidence of 0.2%.

3,3'-Dimethoxybenzidine dihydrochloride consumption led to adenocarcinomas in the mammary gland of females receiving the mid and high doses. The incidence of adenocarcinomas in the high dose group (33%) was four times greater than the highest observed historical incidence in untreated control female F344/N rats. The first neoplasm was observed in a high dose female at week 41, whereas in the female controls, the one adenocarcinoma was observed at termination at week 93. The remarkable increase in adenocarcinomas and decreased time-to-tumor were a direct result of 3,3'-dimethoxybenzidine dihydrochloride exposure.

Intake of 3,3'-dimethoxybenzidine dihydrochloride was associated with increased incidences of hepatocellular neoplasms, principally neoplastic nodules (hepatocellular adenoma), in exposed male rats. Although the increased incidences of neoplasms were not as remarkable in the liver as in the other organs, the dose-related increases in hepatocellular neoplasms in the mid and high dose groups of males and in exposed female rats support the conclusion that 3,3'-dimethoxybenzidine dihydrochloride exposure was responsible for these neoplasms. 3,3'-Dimethoxybenzidine dihydrochloride was also associated with an increase in the incidence of eosinophilic foci in male rats. These foci are believed to be reversible changes that may progress to neoplasia (Maronpot et al., 1986). Because of the relatively high incidences of liver foci observed after exposure to 3,3'-dimethoxybenzidine dihydrochloride for 9 months, higher incidences of liver tumors were expected after exposure for 21 months. The low incidence of liver tumors may have been due in part to the early deaths of many animals because of neoplasia at other sites. In addition, early termination of the studies shortened the time available for liver foci to progress to detectable tumors.

Survival of 3,3'-dimethoxybenzidine dihydrochloride-exposed rats was reduced during the 21-month studies primarily because of moribund animals' being killed with the presence of grossly visible neoplasms of the skin, Zymbal gland, and preputial gland in males and of the Zymbal, clitoral, and mammary glands in females. Tumors of these tissues first appeared in males after 32 weeks of exposure (Zymbal gland) and in females after 32 weeks (clitoral gland).

Early deaths from these neoplasms may have reduced the number of male and female rats at risk for development of tumors at other sites. Mesotheliomas in male rats were associated with 3,3'-dimethoxybenzidine dihydrochloride exposure at the two upper doses. Although increased above that observed in controls, the incidences of these lesions were marginal; however, the lesions might have occurred in more animals if these groups had survived longer. Similarly, in dosed female rats, neoplasms of the skin, oral cavity, intestine, liver, and uterus/cervix occurred at incidences that were only marginally increased; however, the survival of exposed female rats was reduced early in the study by neoplasms of the clitoral, mammary, and Zymbal glands. Because of the low spontaneous incidence of most of these tumors and the chemically related early deaths, neoplasms in these tissues were considered to be related to 3,3'-dimethoxybenzidine dihydrochloride exposure.

The association between 3,3'-dimethoxybenzidine exposure and astrocytomas of the brain in male rats is less strong. The incidence of these tumors was only marginally increased and was not dose related. However, in consideration of the reduced survival of exposed rats and of the low spontaneous occurrence of these tumors,

these neoplasms may have been related to 3,3'-dimethoxybenzidine dihydrochloride exposure.

For these later developing or less rapidly lethal tumors, expression of tumor incidence by the standard convention (the number of tumor-bearing animals at a site divided by the number of animals in which this site was examined) might underestimate the tumor incidence that would have been observed in the absence of early deaths. Therefore, tumor incidence ratios were expressed in terms of the "effective" number of animals actually at risk; i.e., the number of tumor-bearing animals at a particular site divided by the number of animals alive in each group at the time the first tumor was observed at that site in any of the four (control or low, mid, or high dose) groups. These derived incidences were analyzed statistically with the Cochran-Armitage trend test and the Fisher exact test.

Tumor Transplant Study

Because preputial gland neoplasms are usually not overtly aggressive or invasive and rarely metastasize (Goodman et al., 1979; Reznik and Ward, 1981), classification of these neoplasms as benign or malignant is difficult (Maronpot et al., 1988). Studies by Ward and Lynch (1984) showed that malignant preputial/clitoral gland neoplasms from aging F344 rats were transplantable at a higher incidence and with shorter latency periods than benign neoplasms. However, these conclusions were based on a single-passage study with a single carcinoma and four adenomas.

The transplantability of preputial gland neoplasms induced by 3,3'-dimethoxybenzidine dihydrochloride, C.I. Direct Blue 15, or C.I. Acid Red 114 was investigated to provide information on the biologic behavior of these neoplasms (Maronpot et al., 1988; Ulland et al., 1989). All neoplasms selected for transplantation were retrospectively diagnosed as carcinomas, and therefore comparable information was not obtained for preputial gland adenomas. The transplanted preputial gland neoplasms did not become anaplastic or less differentiated over four serial passages; however, the transplants behaved biologically as malignant neoplasms in spite of their well-differentiated morphology. The latency period was short and transplants grew rapidly, reaching 3.0 cm in 7-9 weeks. No differences were observed in morphology or growth of transplants obtained from control or 3,3'-dimethoxybenzidine dihydrochloride-exposed rats. The results of these studies confirm the malignant nature of these preputial gland neoplasms from rats exposed to 3,3'-dimethoxybenzidine dihydrochloride.

Oncogene Activation

Neoplasms obtained from control rats and rats exposed to 3,3'-dimethoxybenzidine dihydrochloride or C.I. Direct Blue 15 (a 3,3'-dimethoxybenzidine-derived dye) were assayed for the presence of activated proto-oncogenes by the NIH 3T3 DNA transfection assay (Anderson et al., 1987). Oncogenes detectable by DNA transfection analysis were present in 21/27 skin, clitoral gland, or preputial gland neoplasms that had been induced by 3,3'-dimethoxybenzidine dihydrochloride or C.I. Direct Blue 15. DNA from both benign and malignant neoplasms was capable of inducing morphologically transformed foci in NIH 3T3 mouse fibroblast cultures.

Thirteen of the chemically induced neoplasm types were of epidermal origin and were classified as basal or squamous cell neoplasms of the skin; activated *ras* oncogenes were detected at a high frequency in these neoplasms (11/13). Histogenetically related neoplasms of the clitoral and preputial glands also had a high frequency of activated *ras* oncogenes (10/14).

It is difficult to compare oncogene activation in spontaneously occurring neoplasms with that in chemical-induced neoplasms because of the substantial difference in the neoplasm types obtained in the two groups. Only 55% (21/38) of the spontaneously occurring neoplasm types were of epithelial cell origin. However, in neoplasms of epithelial cell origin, there is a thirteenfold higher incidence of *ras* gene activation in the chemically induced neoplasms (21/34) than in the spontaneous neoplasms (1/21).

It is possible that chemically induced neoplasms were derived from a common epidermal progenitor stem-cell population that was susceptible to electrophilic attack by activated metabolites of 3,3'-dimethoxybenzidine or C.I. Direct Blue 15. A relatively high percentage (62%) of the chemically induced rat neoplasms contained activated alleles of either H-*ras* or N-*ras*. Those

neoplasms with activated H-*ras* contained point mutations in the 12th, 13th, or 61st codon. The much higher incidence of H-*ras* gene activation and the apparent mutational specificity at codons 13 and 61 of H-*ras* with 3,3'-dimethoxybenzidine exposure suggest that the increased tumor incidence observed in exposed rats is directly related to the genotoxic effect of this chemical.

Related Aromatic Amines

Benzidine and related aromatic amines produce neoplasms in a wide variety of tissues in experimental animals. In humans, exposure to benzidine is associated with cancer of the urinary bladder (Zavon et al., 1973); in mice, however, the liver is the major target organ (Bonser et al., 1956; Vesselinovitch et al., 1975; Littlefield et al., 1983; IARC, 1987a). In rats, benzidine and other aminobiphenyls cause neoplasms in the Zymbal gland, mammary gland, skin, intestine, and liver. These differences in species and target organ specificity may be related to differences in metabolism.

A number of aromatic amines cause neoplasms in the Zymbal gland (Table 23). The Zymbal gland has been reported to be deficient in sulfotransferase activity (Irving et al., 1971) and transacylase activity (Bartsch et al., 1973), but it is capable of hydroxylating compounds via cytochrome P450-dependent enzymatic pathways (Pohl and Fouts, 1983). Susceptibility of a species to the carcinogenic action of aromatic amines depends on the ability of the species to *N*-hydroxylate the amine substituent. *N*-Hydroxylation appears to be a necessary step in the metabolic activation of aromatic amines. *N*-Acyl and *N*-acetyl aromatic amine derivatives require additional activation to reactive esters, which act as ultimate carcinogens (Miller and Miller, 1977). Formation of different esters by different species may result in variations in organ specificity (Cohen, 1983).

Of 350 chemicals evaluated for carcinogenicity in rats and mice by the NCI/NTP, only 14 were associated with Zymbal gland neoplasms in rats. Ten of these 14 chemicals are aryl nitrogen derivatives (nitro, amino, or isocyanate), which were mutagenic for *Salmonella typhimurium*, and produced neoplasms in both rats and mice. In a survey of 222 chemicals evaluated by the NCI/NTP, Ashby and Tennant (1988) reported that only 6 were associated with skin neoplasms after systemic administration. Of these six chemicals, five were aryl nitrogen derivatives and five were among the group of nine chemicals that caused Zymbal gland neoplasms. Although not included in this survey, 3,3'-dimethoxybenzidine dihydrochloride, benzidine, and several other aromatic amines (Table 23) also belong to this group of genotoxic carcinogens that cause Zymbal gland and/or skin neoplasms in rodents.

Audit

The experimental and tabulated data for the NTP Technical Report on 3,3'-dimethoxybenzidine dihydrochloride were examined for accuracy, consistency, completeness, and compliance with Good Laboratory Practice regulations. As summarized in Appendix I, the audit revealed no major problems with the conduct of the studies or with collection and documentation of the experimental data. No discrepancies were found that influenced the final interpretation of the results of these studies.

Conclusions

Under the conditions of these 21-month drinking water studies, there was *clear evidence of carcinogenic activity** of 3,3'-dimethoxybenzidine dihydrochloride for male F344/N rats, as indicated by benign and malignant neoplasms of the skin, Zymbal gland, preputial gland, oral cavity, intestine, liver, and mesothelium. Increased incidences of astrocytomas of the brain may have been related to chemical administration. There was *clear evidence of carcinogenic activity* of 3,3'-dimethoxybenzidine dihydrochloride for female F344/N rats, as indicated by benign and malignant neoplasms of the Zymbal gland, clitoral gland, and mammary gland. Increases in neoplasms of the skin, oral cavity, large intestine, liver, and uterus/cervix were also considered to be related to chemical administration of 3,3'-dimethoxybenzidine dihydrochloride.

*Explanation of Levels of Evidence of Carcinogenic Activity is on page 6.
A summary of the Peer Review comments and the public discussion on this Technical Report appears on page 9.

TABLE 23. STRUCTURAL ANALOGS OF 3,3'-DIMETHOXYBENZIDINE WHICH ARE MUTAGENIC CARCINOGENS FOR RAT ZYMBAL GLAND AND SKIN

Aromatic Amine	Structure	*Salmonella typhimurium* Assay	Zymbal Gland	Skin	References
Benzidine		+	+	–	IARC, 1987a
4-Aminobiphenyl		+	+	–	IARC, 1987b
4,4'-Thiodianiline		+	+	+	NCI, 1978e
Hydrazobenzene		+	+	–	NCI, 1978f
3,3'-Dimethoxybenzidine		+	+	+	Current studies
3,3'-Dimethoxybenzidine diisocyanate		+	+	+	NCI, 1979

TABLE 23. STRUCTURAL ANALOGS OF 3,3'-DIMETHOXYBENZIDINE WHICH ARE MUTAGENIC CARCINOGENS FOR RAT ZYMBAL GLAND AND SKIN (Continued)

Aromatic Amine	Structure	*Salmonella typhimurium* Assay	Zymbal Gland	Skin	References
3,3'-Dimethylbenzidine		+	+	–	Pliss, 1965
3,3'-Dichlorobenzidine		+	+	+	IARC, 1987c; Lazear and Louie, 1977
2,4-Diaminoanisole sulfate		+	+	+	NCI, 1978g
5-Nitro-*o*-anisidine		+	+	+	NCI, 1978h

APPENDIX A

SUMMARY OF LESIONS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

TABLE A1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

	Untreated Control	80 ppm	170 ppm	330 ppm
Animals initially in study	70	45	75	70
Animals removed	70	45	75	70
Animals examined histopathologically	60	45	75	60
ALIMENTARY SYSTEM				
Intestine large, cecum	(60)	(42)	(72)	(58)
Adenocarcinoma, cystic, mucinous				1 (2%)
Rectum, mesothelioma malignant, metastatic	1 (2%)			
Intestine large, colon	(60)	(43)	(73)	(58)
Adenocarcinoma			2 (3%)	
Ascending colon, polyp adenomatous		1 (2%)		
Descending colon, adenocarcinoma			2 (3%)	2 (3%)
Descending colon, polyp adenomatous			3 (4%)	4 (7%)
Descending colon, polyp adenomatous, multiple			1 (1%)	
Intestine large, rectum	(59)	(42)	(73)	(58)
Adenocarcinoma				1 (2%)
Polyp adenomatous				1 (2%)
Intestine small, duodenum	(60)	(42)	(70)	(55)
Adenocarcinoma			1 (1%)	
Adenocarcinoma, cystic, mucinous		2 (5%)	1 (1%)	
Ileum, jejunum, mesothelioma malignant, metastatic, testes	1 (2%)			
Jejunum, mesothelioma malignant, metastatic, testes			1 (1%)	
Intestine small, ileum	(59)	(42)	(69)	(57)
Adenocarcinoma				1 (2%)
Intestine small, jejunum	(59)	(41)	(69)	(56)
Adenocarcinoma			1 (1%)	1 (2%)
Adenocarcinoma, cystic, mucinous		2 (5%)	4 (6%)	3 (5%)
Liver	(60)	(45)	(74)	(60)
Hepatocellular carcinoma	1 (2%)	1 (2%)		2 (3%)
Leukemia mononuclear	19 (32%)	16 (36%)	14 (19%)	2 (3%)
Lymphoma malignant histiocytic			1 (1%)	
Mesothelioma malignant, metastatic, testes	1 (2%)			1 (2%)
Mesothelioma malignant, metastatic, multiple, testes			1 (1%)	
Neoplastic nodule		3 (7%)	7 (9%)	4 (7%)
Neoplastic nodule, multiple				2 (3%)
Mesentery	*(60)	*(45)	*(75)	*(60)
Mesothelioma malignant, metastatic, testes	1 (2%)			2 (3%)
Mesothelioma malignant, metastatic, multiple, testes	1 (2%)		3 (4%)	
Sarcoma	1 (2%)			
Schwannoma malignant			2 (3%)	
Pancreas	(60)	(44)	(75)	(60)
Adenocarcinoma, metastatic, multiple, intestine small		1 (2%)		
Leukemia mononuclear	1 (2%)			
Mesothelioma malignant, metastatic, testes	1 (2%)		1 (1%)	1 (2%)
Mesothelioma malignant, metastatic, multiple, testes			1 (1%)	
Acinus, adenoma		2 (5%)		1 (2%)
Pharynx	*(60)	*(45)	*(75)	*(60)
Carcinoma, metastatic, Zymbal gland				1 (2%)
Mucosa, carcinoma, metastatic, skin				1 (2%)
Palate, carcinoma, metastatic, Zymbal gland				1 (2%)
Palate, papilloma squamous		4 (9%)	5 (7%)	3 (5%)
Palate, squamous cell carcinoma				1 (2%)
Salivary glands	(60)	(44)	(75)	(60)
Schwannoma malignant		2 (5%)		

TABLE A1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

	Untreated Control	80 ppm	170 ppm	330 ppm
ALIMENTARY SYSTEM (Continued)				
Stomach, forestomach	(59)	(44)	(73)	(57)
Leiomyosarcoma			1 (1%)	
Glandular, mesothelioma malignant, metastatic, testes	1 (2%)		1 (1%)	
Tongue	*(60)	*(45)	*(75)	*(60)
Papilloma squamous	1 (2%)	3 (7%)	5 (7%)	7 (12%)
Squamous cell carcinoma		1 (2%)		1 (2%)
Parenchyma, carcinoma	1 (2%)			
CARDIOVASCULAR SYSTEM				
Heart	(60)	(44)	(75)	(60)
Fibrous histiocytoma, metastatic, skin			1 (1%)	
Leukemia mononuclear	4 (7%)	1 (2%)		
Schwannoma benign			1 (1%)	
Schwannoma malignant			1 (1%)	
ENDOCRINE SYSTEM				
Adrenal gland	(60)	(44)	(74)	(60)
Capsule, mesothelioma malignant, metastatic, testes			2 (3%)	
Adrenal gland, cortex	(60)	(44)	(74)	(60)
Leukemia mononuclear	6 (10%)	6 (14%)	2 (3%)	
Bilateral, mesothelioma malignant, metastatic, testes	1 (2%)			
Adrenal gland, medulla	(60)	(44)	(74)	(60)
Leukemia mononuclear	6 (10%)	6 (14%)	2 (3%)	
Pheochromocytoma malignant	2 (3%)	1 (2%)	3 (4%)	
Pheochromocytoma benign	12 (20%)	10 (23%)	16 (22%)	5 (8%)
Bilateral, pheochromocytoma benign	2 (3%)	7 (16%)	7 (9%)	4 (7%)
Islets, pancreatic	(60)	(44)	(75)	(60)
Adenoma	1 (2%)			
Carcinoma		1 (2%)		
Pituitary gland	(58)	(43)	(74)	(59)
Leukemia mononuclear	1 (2%)	2 (5%)		
Schwannoma malignant, metastatic, eye				1 (2%)
Pars distalis, adenoma	2 (3%)	1 (2%)		3 (5%)
Thyroid gland	(60)	(44)	(74)	(60)
C-cell, adenoma	6 (10%)	6 (14%)	5 (7%)	1 (2%)
C-cell, carcinoma		1 (2%)	2 (3%)	1 (2%)
Follicular cell, adenoma				1 (2%)
Follicular cell, carcinoma		1 (2%)		
GENERAL BODY SYSTEM				
Tissue, NOS	*(60)	*(45)	*(75)	*(60)
Mesothelioma malignant, metastatic, testes			1 (1%)	
GENITAL SYSTEM				
Epididymis	(60)	(45)	(75)	(59)
Mesothelioma malignant, metastatic, testes	1 (2%)			
Bilateral, mesothelioma malignant, metastatic, testes	1 (2%)	1 (2%)	6 (8%)	3 (5%)
Preputial gland	(60)	(43)	(73)	(59)
Adenoma	13 (22%)	4 (9%)	17 (23%)	11 (19%)
Carcinoma	2 (3%)	5 (12%)	12 (16%)	17 (29%)
Leukemia mononuclear	1 (2%)			
Bilateral, adenoma	1 (2%)	2 (5%)	2 (3%)	1 (2%)
Bilateral, carcinoma		1 (2%)	3 (4%)	2 (3%)

TABLE A1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

	Untreated Control	80 ppm	170 ppm	330 ppm
GENITAL SYSTEM (Continued)				
Prostate	(60)	(44)	(75)	(60)
Adenoma			1 (1%)	
Mesothelioma malignant, metastatic, testes	1 (2%)		1 (1%)	1 (2%)
Mesothelioma malignant, metastatic, multiple, testes			1 (1%)	
Seminal vesicle	(58)	(42)	(58)	(44)
Adenocarcinoma, metastatic, multiple, intestine small		1 (2%)		
Adenoma				1 (2%)
Leukemia mononuclear	1 (2%)			
Mesothelioma malignant, metastatic, testes	1 (2%)		2 (3%)	
Mesothelioma malignant, metastatic, multiple, testes			1 (2%)	
Bilateral, mesothelioma malignant, metastatic, testes	1 (2%)			
Testes	(60)	(45)	(75)	(59)
Mesothelioma benign				1 (2%)
Mesothelioma malignant				1 (2%)
Bilateral, mesothelioma benign				1 (2%)
Bilateral, mesothelioma malignant	2 (3%)	1 (2%)	7 (9%)	3 (5%)
Bilateral, interstitial cell, adenoma	49 (82%)	35 (78%)	51 (68%)	24 (41%)
Interstitial cell, adenoma	8 (13%)	4 (9%)	17 (23%)	18 (31%)
HEMATOPOIETIC SYSTEM				
Bone marrow	(60)	(43)	(74)	(60)
Leukemia mononuclear	2 (3%)		1 (1%)	
Lymph node	(60)	(43)	(75)	(58)
Axillary, mediastinal, basal cell carcinoma, metastatic, skin				1 (2%)
Deep cervical, carcinoma, metastatic, thyroid gland				1 (2%)
Inguinal, carcinoma, metastatic				1 (2%)
Inguinal, iliac, carcinoma, metastatic, preputial gland				1 (2%)
Mediastinal, fibrous histiocytoma, metastatic, skin			1 (1%)	
Mediastinal, leukemia mononuclear	4 (7%)	3 (7%)	1 (1%)	
Pancreatic, leukemia mononuclear	3 (5%)			
Lymph node, mandibular	(60)	(43)	(74)	(58)
Leukemia mononuclear	5 (8%)	5 (12%)	1 (1%)	
Squamous cell carcinoma, metastatic, skin		1 (2%)		
Lymph node, mesenteric	(59)	(42)	(73)	(56)
Leukemia mononuclear	5 (8%)	3 (7%)		
Mediastinal, pancreatic, adenocarcinoma, metastatic, intestine small		1 (2%)		
Spleen	(60)	(42)	(74)	(59)
Basal cell carcinoma, metastatic, skin				1 (2%)
Hemangiosarcoma				1 (2%)
Leukemia mononuclear	19 (32%)	16 (38%)	17 (23%)	4 (7%)
Lymphoma malignant histiocytic			1 (1%)	
Mesothelioma malignant, metastatic, testes	1 (2%)		2 (3%)	1 (2%)
INTEGUMENTARY SYSTEM				
Mammary gland	(56)	(42)	(68)	(56)
Fibroadenoma	1 (2%)		2 (3%)	
Skin	(60)	(45)	(75)	(60)
Basal cell adenoma	1 (2%)	15 (33%)	12 (16%)	10 (17%)
Basal cell adenoma, multiple		16 (36%)	35 (47%)	25 (42%)
Basal cell carcinoma	1 (2%)	3 (7%)	14 (19%)	13 (22%)
Basal cell carcinoma, multiple		1 (2%)	4 (5%)	4 (7%)
Keratoacanthoma	1 (2%)	5 (11%)	7 (9%)	1 (2%)

TABLE A1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

	Untreated Control	80 ppm	170 ppm	330 ppm
INTEGUMENTARY SYSTEM				
Skin (Continued)	(60)	(45)	(75)	(60)
Papilloma squamous		3 (7%)	7 (9%)	3 (5%)
Papilloma squamous, multiple		2 (4%)		2 (3%)
Squamous cell carcinoma		8 (18%)	15 (20%)	15 (25%)
Squamous cell carcinoma, multiple		1 (2%)	9 (12%)	6 (10%)
Sebaceous gland, adenoma		2 (4%)	2 (3%)	1 (2%)
Sebaceous gland, carcinoma			1 (1%)	1 (2%)
Subcutaneous tissue, carcinoma, metastatic				1 (2%)
Subcutaneous tissue, fibroma		4 (9%)	4 (5%)	1 (2%)
Subcutaneous tissue, fibroma, multiple				1 (2%)
Subcutaneous tissue, fibrosarcoma				1 (2%)
Subcutaneous tissue, fibrous histiocytoma			1 (1%)	
Subcutaneous tissue, neurofibroma		2 (4%)	2 (3%)	2 (3%)
Subcutaneous tissue, sarcoma	2 (3%)			
MUSCULOSKELETAL SYSTEM				
Bone	*(60)	*(45)	*(75)	*(60)
Chordoma		1 (2%)		
Cranium, carcinoma, metastatic, Zymbal gland		1 (2%)		5 (8%)
Cranium, squamous cell carcinoma, metastatic				1 (2%)
Cranium, squamous cell carcinoma, metastatic, skin		1 (2%)		
Skeletal muscle	*(60)	*(45)	*(75)	*(60)
Abdominal, schwannoma malignant, metastatic, mesentery			2 (3%)	
Cervical, carcinoma, metastatic, Zymbal gland				1 (2%)
Thoracic, fibrous histiocytoma, metastatic, skin			1 (1%)	
NERVOUS SYSTEM				
Brain	(60)	(44)	(75)	(60)
Astrocytoma malignant			1 (1%)	
Leukemia mononuclear	3 (5%)	1 (2%)		
Cerebellum, astrocytoma malignant		1 (2%)		
Cerebellum, cerebrum, astrocytoma malignant			1 (1%)	
Cerebrum, astrocytoma malignant		1 (2%)	1 (1%)	1 (2%)
Meninges, cerebrum, perivascular, squamous cell carcinoma, metastatic, skin		1 (2%)		
RESPIRATORY SYSTEM				
Lung	(60)	(44)	(75)	(60)
Adenocarcinoma, metastatic, multiple, intestine small		1 (2%)		
Alveolar/bronchiolar adenoma			2 (3%)	1 (2%)
Basal cell carcinoma, metastatic, multiple, skin		1 (2%)		1 (2%)
Carcinoma, metastatic, preputial gland			1 (1%)	
Carcinoma, metastatic, Zymbal gland		1 (2%)	1 (1%)	1 (2%)
Carcinoma, metastatic, multiple, preputial gland				1 (2%)
Carcinoma, metastatic, multiple, Zymbal gland		1 (2%)		2 (3%)
Fibrosarcoma, metastatic, multiple, skin				1 (2%)
Fibrous histiocytoma, metastatic, skin			1 (1%)	
Leukemia mononuclear	9 (15%)	10 (23%)	8 (11%)	
Lymphoma malignant histiocytic			1 (1%)	
Squamous cell carcinoma, metastatic, skin				2 (3%)
Squamous cell carcinoma, metastatic, multiple, skin		1 (2%)		1 (2%)
Nose	(60)	(44)	(74)	(60)
Adenoma			1 (1%)	
Squamous cell carcinoma, metastatic, skin		1 (2%)		
Submucosa, schwannoma malignant, metastatic, eye				1 (2%)

TABLE A1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

	Untreated Control	80 ppm	170 ppm	330 ppm
SPECIAL SENSES SYSTEM				
Eye	*(60)	*(45)	*(75)	*(60)
Choroid, conjunctiva, retrobulbar, squamous cell carcinoma, metastatic, skin		1 (2%)		
Optic nerve, schwannoma malignant				1 (2%)
Zymbal gland	(59)	(45)	(75)	(60)
Adenoma		3 (7%)	11 (15%)	9 (15%)
Carcinoma		7 (16%)	13 (17%)	20 (33%)
Bilateral, adenoma		1 (2%)		
Bilateral, carcinoma			1 (1%)	1 (2%)
URINARY SYSTEM				
Kidney	(60)	(44)	(74)	(60)
Adenocarcinoma, metastatic, intestine small		1 (2%)		
Leukemia mononuclear	4 (7%)	1 (2%)	2 (3%)	
Mesothelioma malignant, metastatic, testes	1 (2%)		1 (1%)	1 (2%)
Mesothelioma malignant, metastatic, multiple, testes			1 (1%)	
Bilateral, mesothelioma malignant, metastatic, testes	1 (2%)			
Urinary bladder	(60)	(44)	(75)	(59)
Leukemia mononuclear	1 (2%)			
Mesothelioma malignant, metastatic, testes	1 (2%)		2 (3%)	2 (3%)
SYSTEMIC LESIONS				
Multiple organs	*(60)	*(45)	*(75)	*(60)
Mesothelioma malignant	2 (3%)	1 (2%)	7 (9%)	4 (7%)
Leukemia mononuclear	19 (32%)	17 (38%)	17 (23%)	4 (7%)
Lymphoma malignant histiocytic			1 (1%)	
Mesothelioma benign				2 (3%)
Hemangiosarcoma				1 (2%)
ANIMAL DISPOSITION SUMMARY				
Animals initially in study	70	45	75	70
Interval sacrifice	10			10
Terminal sacrifice	44	8		
Dead	9	9	25	14
Moribund	7	28	50	46
TUMOR SUMMARY				
Total animals with primary neoplasms **	59	45	75	60
Total primary neoplasms	129	194	344	254
Total animals with benign neoplasms	57	43	70	53
Total benign neoplasms	98	135	223	149
Total animals with malignant neoplasms	27	36	66	59
Total malignant neoplasms	31	59	121	105
Total animals with secondary neoplasms ***	2	6	11	19
Total secondary neoplasms	17	16	36	39

* Number of animals receiving complete necropsy examination; all gross lesions including masses examined microscopically.
** Primary tumors: all tumors except secondary tumors
*** Secondary tumors: metastatic tumors or tumors invasive into an adjacent organ

TABLE A3. ANALYSIS OF PRIMARY TUMORS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

(a) Number of tumor-bearing animals/number of animals examined microscopically at the site
(b) Number of tumor-bearing animals/effective number of animals, i.e., number of animals alive at the first occurrence of tumors in any of the four groups
(c) Observed tumor incidence in animals killed at the end of the study
(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the effective tumor rates. A negative trend or a lower incidence in a dosed group than in controls is indicated by (N).
(e) Number of tumor-bearing animals/number of animals examined grossly at the site
(f) No P value is reported because no tumors were observed in the dosed and control groups.

TABLE A4a. HISTORICAL INCIDENCE OF LIVER TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence in Controls		
	Neoplastic Nodule	Hepatocellular Carcinoma	Neoplastic Nodule or Hepatocellular Carcinoma
Historical Incidence at Hazleton Laboratories America, Inc.			
Decabromodiphenyl oxide	1/50	1/50	2/50
Chlorendic acid	2/50	3/50	5/50
TOTAL	3/100 (3.0%)	4/100 (4.0%)	7/100 (7.0%)
Overall Historical Incidence

SD (b)	4.18%	1.52%	4.34%
Range (c)			
High	6/49	3/50	7/49
Low	0/50	0/50	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Standard deviation
(c) Range and SD are presented for groups of 35 or more animals.

TABLE A4b. HISTORICAL INCIDENCE OF TUMORS OF THE LARGE INTESTINE IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence of Adenocarcinomas in Controls
Historical Incidence at Hazleton Laboratories America, Inc.	
Decabromodiphenyl oxide	0/47
Chlorendic acid	0/49
TOTAL	0/96
Overall Historical Incidence	
TOTAL	(b) 2/1,541 (0.1%)
SD (c)	0.50%
Range (d)	
High	1/49
Low	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Mucinous adenocarcinomas; no benign tumors have been observed.
(c) Standard deviation
(d) Range and SD are presented for groups of 35 or more animals.

TABLE A4c. HISTORICAL INCIDENCE OF TUMORS OF THE SMALL INTESTINE IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence of Adenocarcinomas in Controls
Historical Incidence at Hazleton Laboratories America, Inc.	
Decabromodiphenyl oxide	(b) 1/49
Chlorendic acid	0/48
TOTAL	1/97 (1.0%)
Overall Historical Incidence	
TOTAL	(c) 5/1,557 (0.3%)
SD (d)	0.77%
Range (e)	
High	1/44
Low	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Carcinoma, NOS
(c) Includes one carcinoma, NOS, three adenocarcinomas, NOS, and one mucinous adenocarcinoma; no benign tumors have been observed.
(d) Standard deviation
(e) Range and SD are presented for groups of 35 or more animals.

TABLE A4d. HISTORICAL INCIDENCE OF ZYMBAL GLAND TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence of Adenomas or Carcinomas in Controls
Historical Incidence at Hazleton Laboratories America, Inc.	
Decabromodiphenyl oxide	0/50
Chlorendic acid	(b) 1/50
TOTAL	(b) 1/100 (1.0%)
Overall Historical Incidence	
TOTAL	(c) 19/1,596 (1.2%)
SD (d)	1.82%
Range (e)	
High	4/50
Low	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Carcinoma, NOS
(c) Includes 1 papillary adenoma, 11 carcinomas, NOS, and 7 squamous cell carcinomas
(d) Standard deviation
(e) Range and SD are presented for groups of 35 or more animals.

TABLE A4e. HISTORICAL INCIDENCE OF PREPUTIAL GLAND TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence in Controls		
	Adenoma	Carcinoma	Adenoma or Carcinoma
Historical Incidence at Hazleton Laboratories America, Inc.

Range (d)			
High	2/49	2/49	3/49
Low	0/50	0/50	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Includes one papilloma, NOS
(c) Standard deviation
(d) Range and SD are presented for groups of 35 or more animals.

TABLE A4j. HISTORICAL INCIDENCE OF BRAIN GLIAL CELL TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence in Controls
Historical Incidence at Hazleton Laboratories America, Inc.	
Decabromodiphenyl oxide	2/50
Chlorendic acid	0/50
TOTAL	(b) 2/100 (2.0%)
Overall Historical Incidence	
TOTAL	(c) 14/1,590 (0.9%)
SD (d)	1.43%
Range (e)	
High	2/50
Low	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Astrocytomas
(c) Includes 10 astrocytomas, 3 gliomas, NOS, and 1 oligodendroglioma
(d) Standard deviation
(e) Range and SD are presented for groups of 35 or more animals.

TABLE A4k. HISTORICAL INCIDENCE OF MESOTHELIAL TUMORS IN MALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence of Mesotheliomas in Controls
Historical Incidence at Hazleton Laboratories America, Inc.	
Decabromodiphenyl oxide	1/50
Chlorendic acid	2/50
TOTAL	(b) 3/100 (3.0%)
Overall Historical Incidence	
TOTAL	(c) 47/1,596 (2.9%)
SD (d)	2.65%
Range (e)	
High	5/50
Low	0/50

(a) Data as of May 12, 1988, for studies of at least 104 weeks
(b) Includes two malignant mesotheliomas
(c) Includes 11 malignant mesotheliomas
(d) Standard deviation
(e) Range and SD are presented for groups of 35 or more animals.

TABLE A5. SUMMARY OF THE INCIDENCE OF NONNEOPLASTIC LESIONS IN MALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE

	Untreated Control	80 ppm	170 ppm	330 ppm
Animals initially in study	70	45	75	70
Animals removed	70	45	75	70
Animals examined histopathologically	60	45	75	60

TABLE B1. SUMMARY OF THE INCIDENCE OF NEOPLASMS IN FEMALE RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDY OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (Continued)

	Untreated Control	80 ppm	170 ppm	330 ppm
SPECIAL SENSES SYSTEM				
Zymbal gland	(60)	(45)	(75)	(60)
Adenoma		3 (7%)	4 (5%)	3 (5%)
Carcinoma	1 (2%)	10 (22%)	17 (23%)	10 (17%)
Bilateral, carcinoma				3 (5%)
URINARY SYSTEM				
Kidney	(60)	(45)	(75)	(60)
Leukemia mononuclear	5 (8%)	1 (2%)	1 (1%)	
Lipoma	2 (3%)			
Renal tubule, adenoma		1 (2%)		
Renal tubule, carcinoma, metastatic, urinary bladder				1 (2%)
Transitional epithelium, carcinoma				1 (2%)
Ureter	*(60)	*(45)	*(75)	*(60)
Carcinoma, metastatic, urinary bladder				1 (2%)
Urinary bladder	(60)	(45)	(75)	(59)
Leukemia mononuclear	1 (2%)			
Sarcoma stromal, metastatic, uterus				1 (2%)
Transitional epithelium, carcinoma				1 (2%)
SYSTEMIC LESIONS				
Multiple organs	*(60)	*(45)	*(75)	*(60)
Leukemia mononuclear	21 (35%)	15 (33%)	12 (16%)	4 (7%)
Lymphoma malignant lymphocytic			1 (1%)	
ANIMAL DISPOSITION SUMMARY				
Animals initially in study	70	45	75	70
Interval sacrifice	10			10
Terminal sacrifice	45	15	6	
Moribund	10	27	60	51
Dead	5	3	9	9
TUMOR SUMMARY				
Total animals with primary neoplasms **	48	42	73	57
Total primary neoplasms	84	113	151	132
Total animals with benign neoplasms	35	30	32	34
Total benign neoplasms	53	61	55	54
Total animals with malignant neoplasms	27	32	68	56
Total malignant neoplasms	31	52	96	78
Total animals with secondary neoplasms ***	1	3	7	4
Total secondary neoplasms	1	4	16	14
Total animals with malignant neoplasms--uncertain primary site		1		

* Number of animals receiving complete necropsy examination; all gross lesions including masses examined microscopically.
** Primary tumors: all tumors except secondary tumors
*** Secondary tumors: metastatic tumors or tumors invasive into an adjacent organ

Cochran-Armitage Trend Test (d)	P=0.005N			
Fisher Exact Test (d)		P=0.521N	P=0.150N	P=0.008N

(a) Number of tumor-bearing animals/number of animals examined microscopically at the site
(b) Number of tumor-bearing animals/effective number of animals, i.e., number of animals alive at the first occurrence of tumors in any of the four groups
(c) Observed tumor incidence in animals killed at the end of the study
(d) Beneath the control incidence are the P values associated with the trend test. Beneath the dosed group incidence are the P values corresponding to pairwise comparisons between that dosed group and the controls. The life table analysis regards tumors in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The incidental tumor test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the effective tumor rates. A negative trend or a lower incidence in a dosed group than in controls is indicated by (N).
(e) Number of tumor-bearing animals/number of animals examined grossly at the site
(f) No P value is reported because no tumors were observed in the dosed and control groups.

TABLE B4a. HISTORICAL INCIDENCE OF LIVER TUMORS IN FEMALE F344/N RATS RECEIVING NO TREATMENT (a)

Study	Incidence in Controls	
	Neoplastic Nodule	Neoplastic Nodule or Hepatocellular Carcinoma
Historical Incidence at Hazleton Laboratories America, Inc.		
Decabromodiphenyl oxide	1/50	1/50
Chlorendic acid	1/50	1/50

APPENDIX C

SENTINEL ANIMAL PROGRAM

APPENDIX C. SENTINEL ANIMAL PROGRAM

Methods

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via serology on sera from extra (sentinel) animals in the study rooms. These animals are untreated, and these animals and the study animals are both subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Fifteen F344/N rats of each sex were selected at the time of randomization and allocation of the animals to the various study groups. Five animals of each designated sentinel group were killed at 6, 12, and 18 months on study. Data from animals surviving 21 months were collected from 5/60 randomly selected control animals of each sex. The blood from each animal was collected and clotted, and the serum was separated. The serum was cooled on ice and shipped to Microbiological Associates' Comprehensive Animal Diagnostic Service for determination of the antibody titers. The following tests were performed:

Hemagglutination Inhibition	ELISA
PVM (6,12,18 mo)	RCV/SDA (rat coronavirus/sialodacryoadenitis virus)
KRV (Kilham rat virus)	Sendai (21 mo)
H-1 (Toolan's H-1 virus)	PVM (21 mo)
Sendai (6,12,18 mo)	*M. arth.* (*Mycoplasma arthriditis*) (21 mo)
	M. pul. (*Mycoplasma pulmonis*) (21 mo)

Results

Results are presented in Table C1.

TABLE C1. MURINE ANTIBODY DETERMINATIONS FOR RATS IN THE TWENTY-ONE-MONTH DRINKING WATER STUDIES OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (a)

Interval (months)	Number of Animals	Positive Serologic Reaction for
6	10/10	PVM
	10/10	Sendai
	10/10	RCV/SDA
12	10/10	PVM
	9/10	Sendai
	6/10	RCV/SDA
18	9/9	PVM
	3/9	Sendai
	8/9	RCV/SDA
21	10/10	PVM
	8/10	Sendai
	7/10	RCV/SDA

(a) Blood samples were taken from sentinel animals at 6, 12, and 18 months after the start of dosing and from the control animals just before they were killed; samples were sent to Microbiological Associates, Inc. (Bethesda, MD) for determination of antibody titers.

(a) Grams of water consumed per animal per day; not corrected for wastage.
(b) Estimated milligrams of 3,3'-dimethoxybenzidine dihydrochloride consumed per day per kilogram of body weight
(c) Standard deviation
(d) Coefficient of variation = (standard deviation/mean) × 100

APPENDIX E

INGREDIENTS, NUTRIENT COMPOSITION, AND CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION

Pelleted Diet: January 1983 to December 1984

(Manufactured by Zeigler Bros., Inc., Gardners, PA)

TABLE E1. INGREDIENTS OF NIH 07 RAT AND MOUSE RATION (a)

Ingredients (b)	Percent by Weight
Ground #2 yellow shelled corn	24.50
Ground hard winter wheat	23.00
Soybean meal (49% protein)	12.00
Fish meal (60% protein)	10.00
Wheat middlings	10.00
Dried skim milk	5.00
Alfalfa meal (dehydrated, 17% protein)	4.00
Corn gluten meal (60% protein)	3.00
Soy oil	2.50
Dried brewer's yeast	2.00
Dry molasses	1.50
Dicalcium phosphate	1.25
Ground limestone	0.50
Salt	0.50
Premixes (vitamin and mineral)	0.25

(a) NCI, 1976; NIH, 1978
(b) Ingredients ground to pass through a U.S. Standard Screen No. 16 before being mixed

TABLE E2. VITAMINS AND MINERALS IN NIH 07 RAT AND MOUSE RATION (a)

	Amount	Source
Vitamins		
A	5,500,000 IU	Stabilized vitamin A palmitate or acetate
D_3	4,600,000 IU	D-activated animal sterol
K_3	2.8 g	Menadione
d-α-Tocopheryl acetate	20,000 IU	
Choline	560.0 g	Choline chloride
Folic acid	2.2 g	
Niacin	30.0 g	
d-Pantothenic acid	18.0 g	*d*-Calcium pantothenate
Riboflavin	3.4 g	
Thiamine	10.0 g	Thiamine mononitrate
B_{12}	4,000 µg	
Pyridoxine	1.7 g	Pyridoxine hydrochloride
Biotin	140.0 mg	*d*-Biotin
Minerals		
Iron	120.0 g	Iron sulfate
Manganese	60.0 g	Manganous oxide
Zinc	16.0 g	Zinc oxide
Copper	4.0 g	Copper sulfate
Iodine	1.4 g	Calcium iodate
Cobalt	0.4 g	Cobalt carbonate

(a) Per ton (2,000 lb) of finished product

TABLE E3. NUTRIENT COMPOSITION OF NIH 07 RAT AND MOUSE RATION

Nutrients	Mean ± Standard Deviation	Range	Number of Samples
Protein (percent by weight)	22.78 ± 0.84	21.3-24.9	24
Crude fat (percent by weight)	5.29 ± 0.75	3.3-6.5	24
Crude fiber (percent by weight)	3.45 ± 0.28	2.8-3.8	24
Ash (percent by weight)	6.67 ± 0.40	6.2-7.3	24
Amino Acids (percent of total diet)			
Arginine	1.320 ± 0.072	1.310-1.390	5
Cystine	0.319 ± 0.088	0.218-0.400	5
Glycine	1.146 ± 0.063	1.060-1.210	5
Histidine	0.571 ± 0.026	0.531-0.603	5
Isoleucine	0.914 ± 0.030	0.881-0.944	5
Leucine	1.946 ± 0.056	1.850-1.990	5
Lysine	1.280 ± 0.067	1.200-1.370	5
Methionine	0.436 ± 0.165	0.306-0.699	5
Phenylalanine	0.938 ± 0.158	0.665-1.050	5
Threonine	0.855 ± 0.035	0.824-0.898	5
Tryptophan	0.277 ± 0.221	0.156-0.671	5
Tyrosine	0.618 ± 0.086	0.564-0.769	5
Valine	1.108 ± 0.043	1.050-1.170	5
Essential Fatty Acids (percent of total diet)			
Linoleic	2.290 ± 0.313	1.83-2.52	5
Linolenic	0.258 ± 0.040	0.210-0.308	5
Vitamins			
Vitamin A (IU/kg)	12,379 ± 4,800	4,100-24,000	24
Vitamin D (IU/kg)	4,450 ± 1,382	3,000-6,300	4
α-Tocopherol (ppm)	43.58 ± 6.92	31.1-48.0	5
Thiamine (ppm)	19.10 ± 3.78	12.0-27.0	24
Riboflavin (ppm)	7.6 ± 0.85	6.10-8.20	5
Niacin (ppm)	97.8 ± 31.68	65.0-150.0	5
Pantothenic acid (ppm)	30.06 ± 4.31	23.0-34.0	5
Pyridoxine (ppm)	7.68 ± 1.31	5.60-8.80	5
Folic acid (ppm)	2.62 ± 0.89	1.80-3.70	5
Biotin (ppm)	0.254 ± 0.053	0.19-0.32	5
Vitamin B_{12} (ppb)	24.21 ± 12.66	10.6-38.0	5
Choline (ppm)	3,122 ± 416.8	2,400-3,430	5
Minerals			
Calcium (percent)	1.26 ± 0.14	0.95-1.54	24
Phosphorus (percent)	0.96 ± 0.06	0.87-1.10	24
Potassium (percent)	0.900 ± 0.098	0.772-0.971	3
Chloride (percent)	0.513 ± 0.114	0.380-0.635	5
Sodium (percent)	0.323 ± 0.043	0.258-0.371	5
Magnesium (percent)	0.167 ± 0.012	0.151-0.181	5
Sulfur (percent)	0.304 ± 0.064	0.268-0.420	5
Iron (ppm)	410.3 ± 94.04	262.0-523.0	5
Manganese (ppm)	90.29 ± 7.15	81.7-99.4	5
Zinc (ppm)	52.78 ± 4.94	46.1-58.2	5
Copper (ppm)	10.72 ± 2.76	8.09-15.39	5
Iodine (ppm)	2.95 ± 1.05	1.52-3.82	4
Chromium (ppm)	1.85 ± 0.25	1.44-2.09	5
Cobalt (ppm)	0.681 ± 0.14	0.490-0.780	4

TABLE E4. CONTAMINANT LEVELS IN NIH 07 RAT AND MOUSE RATION

Contaminants	Mean ± Standard Deviation	Range	Number of Samples
Arsenic (ppm)	0.56 ± 0.18	0.17-0.77	24
Cadmium (ppm) (a)	<0.10		24
Lead (ppm)	0.60 ± 0.23	0.33-1.32	24
Mercury (ppm) (a)	<0.05		24
Selenium (ppm)	0.33 ± 0.06	0.21-0.42	24
Aflatoxins (ppb)	<5.0		24
Nitrate nitrogen (ppm) (b)	9.71 ± 4.98	0.10-22.0	24
Nitrite nitrogen (ppm) (b)	1.02 ± 1.68	0.10-7.20	24
BHA (ppm) (c)	2.13 ± 0.61	2.00-5.00	24
BHT (ppm) (c)	2.17 ± 1.67	1.00-4.00	24
Aerobic plate count (CFU/g) (d)	48,263 ± 38,232	7,100-130,000	24
Coliform (MPN/g) (e)	41.42 ± 102	3.00-460	24
E. coli (MPN/g) (f)	3.04 ± 0.20	<3.00-4.00	24
Total nitrosamines (ppb) (g)	5.77 ± 5.82	1.80-30.90	24
N-Nitrosodimethylamine (ppb) (g)	4.76 ± 5.84	0.80-30.00	24
N-Nitrosopyrrolidine (ppb) (g)	1.02 ± 0.20	0.90-1.70	24
Pesticides (ppm)			
α-BHC (a,h)	<0.01		24
β-BHC (a)	<0.02		24
γ-BHC (a)	<0.01		24
δ-BHC (a)	<0.01		24
Heptachlor (a)	<0.01		24
Aldrin (a)	<0.01		24
Heptachlor epoxide (a)	<0.01		24
DDE (a)	<0.01		24
DDD (a)	<0.01		24
DDT (a)	<0.01		24
HCB (a)	<0.01		24
Mirex (a)	<0.01		24
Methoxychlor (a)	<0.05		24
Dieldrin (a)	<0.01		24
Endrin (a)	<0.01		24
Telodrin (a)	<0.01		24
Chlordane (a)	<0.05		24
Toxaphene (a)	<0.1		24
Estimated PCBs (a)	<0.2		24
Ronnel (a)	<0.01		24
Ethion (a)	<0.02		24
Trithion (a)	<0.05		24
Diazinon (a)	<0.1		24
Methyl parathion (a)	<0.02		24
Ethyl parathion (a)	<0.02		24
Malathion (i)	0.10 ± 0.09	0.05-0.45	24
Endosulfan I (a)	<0.01		24
Endosulfan II (a)	<0.01		24
Endosulfan sulfate (a)	<0.03		24

(a) All values were less than the detection limit, given in the table as the mean.
(b) Source of contamination: alfalfa, grains, and fish meal
(c) Source of contamination: soy oil and fish meal
(d) CFU = colony-forming unit
(e) MPN = most probable number
(f) One lot dated October contained 4 MPN/g.
(g) All values were corrected for percent recovery.
(h) BHC = hexachlorocyclohexane or benzene hexachloride
(i) Thirteen lots contained more than 0.05 ppm.

APPENDIX G

CHEMICAL CHARACTERIZATION, ANALYSIS, AND PREPARATION OF FORMULATED DRINKING WATER MIXTURES OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE FOR THE TOXICOLOGY STUDIES

APPENDIX G. CHEMICAL CHARACTERIZATION

Procurement and Characterization of 3,3'-Dimethoxybenzidine Dihydrochloride

A single lot of 3,3'-dimethoxybenzidine dihydrochloride (lot no. 11F-5034) was obtained from Sigma Chemical Company (St. Louis, MO) in two batches: batch no. 1 on February 2, 1981, and batch no. 2 on October 14, 1981. Purity and identity analyses were conducted at Midwest Research Institute (MRI) (Kansas City, MO). MRI reports on the analyses performed in support of the 3,3'-dimethoxybenzidine dihydrochloride studies are on file at the National Institute of Environmental Health Sciences.

The study chemical in both batches was identified as 3,3'-dimethoxybenzidine dihydrochloride by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy. All spectra were consistent with those expected for the structure and with literature references (Sadtler Standard Spectra), except for a minor impurity peak in the nuclear magnetic resonance spectrum and a small unresolved absorbance between 400 and 350 nm in the ultraviolet/visible spectrum.

The purity of lot no. 11F-5034 was determined by elemental analysis, Karl Fischer water analysis, potentiometric titration of the two amine groups in a glacial acetic acid:acetone medium containing mercury (II) acetate with 0.1 N perchloric acid, thin-layer chromatography, and high-performance liquid chromatography. Thin-layer chromatography was performed with chloroform:methyl ethyl ketone:methanol:concentrated ammonium hydroxide (50:30:19:1) on silica gel plates (system 1) and methanol:water:concentrated ammonium hydroxide (80:18:2) on Whatman $KC_{18}F$ plates (system 2). High-performance liquid chromatography was performed by ultraviolet detection at 280 nm with a Waters μBondapak C_{18} column and a solvent system of aqueous 5 mM heptanesulfonic acid sodium salt adjusted to pH 2 with concentrated phosphoric acid:5 mM heptanesulfonic acid sodium salt in methanol with the same volume of phosphoric acid (80:20) (batch no. 1) or aqueous 10 mM heptanesulfonic acid adjusted to pH 2.1 with concentrated phosphoric acid:10 mM heptanesulfonic acid in methanol containing the same volume of phosphoric acid (61:39) (batch no. 2), with detection at 254 nm.

For batch no. 1, the results of elemental analysis for carbon, hydrogen, chlorine, and nitrogen were in agreement with the theoretical values. The presence of 0.66% water was determined by Karl Fischer analysis. Nonaqueous titration of the two amine groups indicated a purity of 97.5%. Thin-layer chromatography indicated a trace impurity at the origin by each system. High-performance liquid chromatography indicated no impurities with individual peak areas greater than or equal to 0.1% of the major peak area.

For batch no. 2, the results of elemental analysis for hydrogen were slightly high. Karl Fischer analysis indicated the presence of 1.1% water. Nonaqueous titration indicated a purity of 98.1%. A trace impurity was observed at the origin by both thin-layer chromatographic systems. High-performance liquid chromatography indicated one impurity with a relative area 0.10% that of the major peak. Comparison of batch no. 1 and batch no. 2 by high-performance liquid chromatography indicated no significant differences between the two batches.

Stability studies performed by high-performance liquid chromatography with the same system as before, but with a solvent ratio of 76:24 and with acetanilide added to the methanol-based solvent as an internal standard, indicated that 3,3'-dimethoxybenzidine dihydrochloride was stable as a bulk chemical when stored protected from light at temperatures up to 60° C. The samples stored at 60° C were different in appearance, indicating possible decomposition. During the 21-month studies, the stability of the bulk chemical was confirmed by high-performance liquid chromatography and nonaqueous titration of the amine groups.

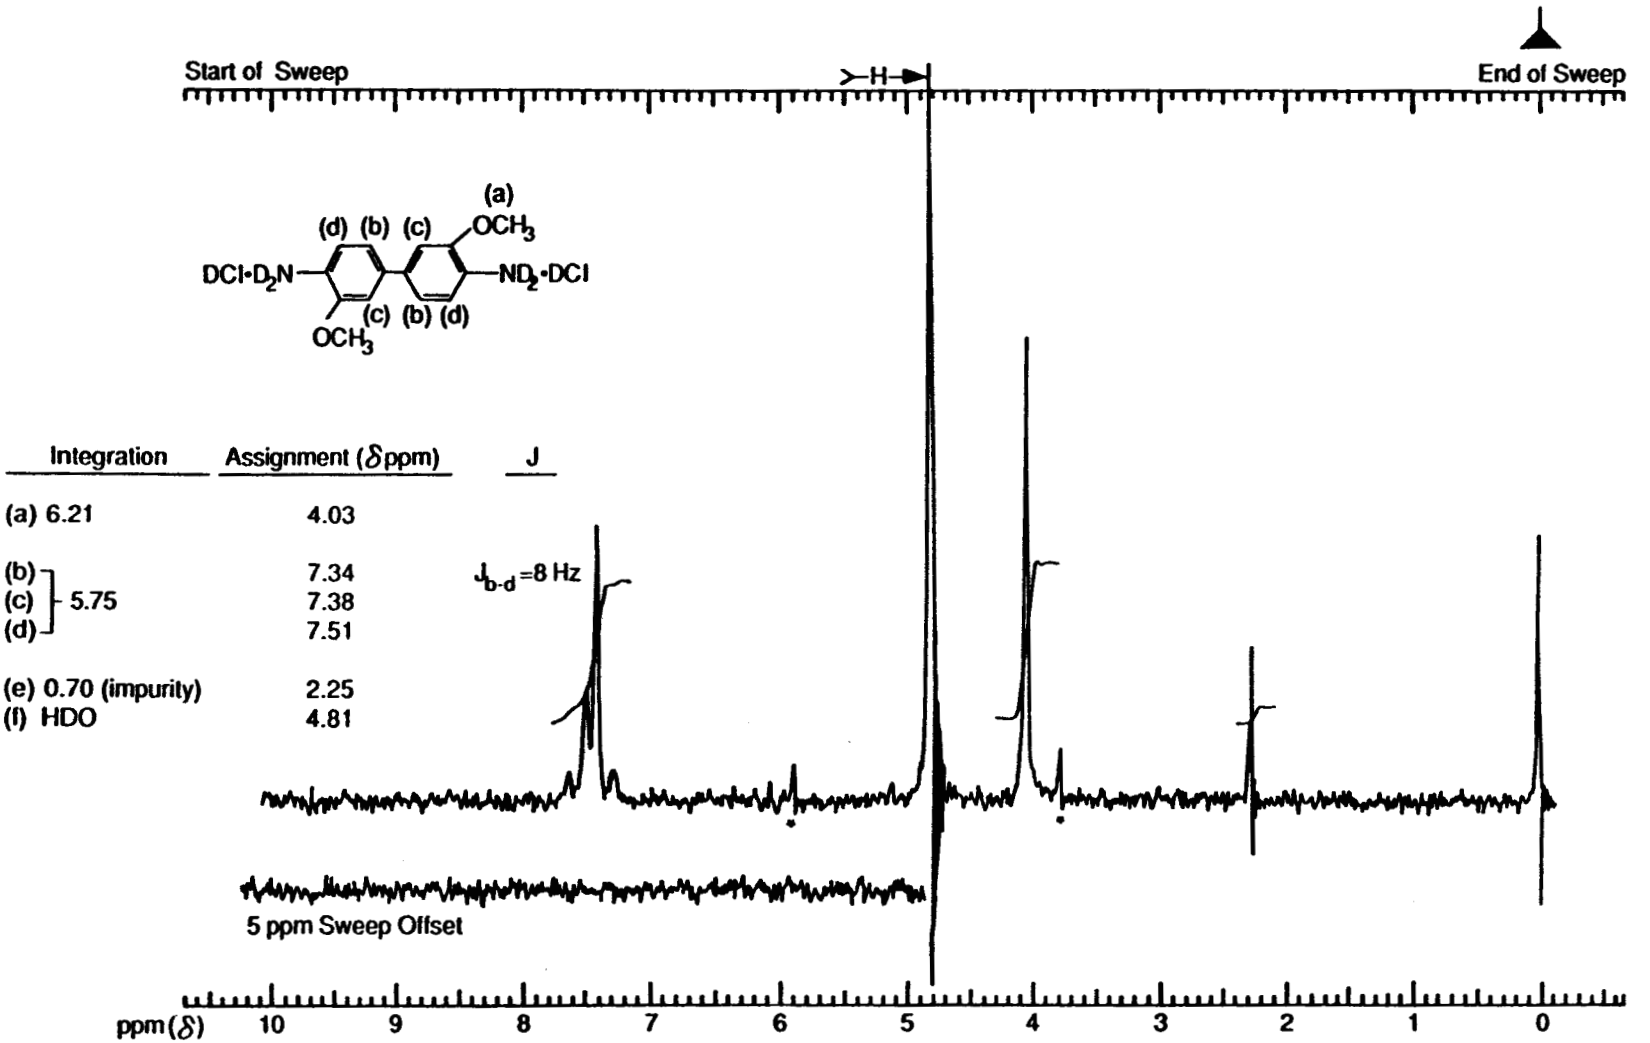

FIGURE G2. NUCLEAR MAGNETIC RESONANCE SPECTRUM OF 3,3'-DIMETHOXYBENZIDINE DIHYDROCHLORIDE (LOT NO. 11F-5034)

The stability of 3,3'-dimethoxybenzidine dihydrochloride in feed (200 ppm) was determined by extracting the stored feed samples with methanol:10% sodium hydroxide (19:1) followed by neutralization with 0.5 N hydrochloric acid, washing with cyclohexane, adjusting to basic pH with 10 N sodium hydroxide, and extraction with methylene chloride. The methylene chloride extract was analyzed by gas chromatography with a 3% OV-17 column and flame ionization detection. 3,3'-Dimethylbenzidine was used as an internal standard. 3,3'-Dimethoxybenzidine dihydrochloride was unstable in NIH 07 Rat and Mouse Ration (200 ppm) under all storage conditions at or above 5° C. Formulated diets stored open to air and light under simulated dosing conditions lost 12% or 18% of the chemical after 3 or 7 days, respectively. The same feed stored in the dark in sealed containers lost 2%, 9%, or 26% of the chemical after storage for 14 days at −20° C, 5° C, or room temperature. Based on these results, drinking water was selected as the route of chemical administration.

Preparation and Characterization of Formulated Drinking Water Mixtures

The appropriate amounts of 3,3'-dimethoxybenzidine dihydrochloride and tap or distilled (21 month) water were mixed (w/v) to give the desired concentrations (Table G1). The stability of 3,3'-dimethoxybenzidine dihydrochloride in drinking water (200 ppm) was determined by high-performance liquid chromatography on a Waters μBondapak C_{18} column and a Whatman Co:PELL ODS guard column with detection at 280 nm after filtration of the solution through a 0.5-μ filter and with propiophenone as an internal standard. The mobile phase was water:methanol (55:45) containing 0.06 N sodium bromide. 3,3'-Dimethoxybenzidine dihydrochloride was found to be stable in water solutions after 14 days' storage at room temperature in the dark in sealed containers. Storage of the solutions in rat cage water bottles exposed to normal room light for 48 hours had no measurable effect on stability. Drinking water mixtures were prepared two times per week and were used immediately or, for the 21-month studies, stored for up to 7 days at room temperature before being used.

Periodic analysis of formulated 3,3'-dimethoxybenzidine dihydrochloride/drinking water mixtures was conducted at the study laboratory and the analytical chemistry laboratory by ultraviolet spectroscopy at 294 nm. Drinking water mixtures were analyzed 1 week before the studies began and three times during the 13-week studies (Table G2). Results of triplicate analysis by the analytical chemistry laboratory (653 ppm) of the 630-ppm drinking water mixture of June 9, 1982, indicated good agreement with those of the study laboratory (650 ppm).

During the 21-month studies, the drinking water mixtures were analyzed at approximately 4-week intervals. Data on the number of times that concentrations were within specifications can be extrapolated to indicate the frequency with which mixtures were formulated within the specified ±10% of the target concentrations. For the 3,3'-dimethoxybenzidine dihydrochloride studies, the mixtures were formulated within ±10% of the target concentrations approximately 99% (103/104) of the time throughout the studies (Table G3). Results of periodic referee analysis performed by the analytical chemistry laboratory indicated good agreement with the results from the study laboratory (Table G4).

APPENDIX H

GENETIC TOXICOLOGY OF

3,3′-DIMETHOXYBENZIDINE

APPENDIX H. GENETIC TOXICOLOGY

METHODS

Salmonella Protocol: Testing was performed as reported by Ames et al. (1975) with modifications listed below and described in greater detail by Haworth et al. (1983). Chemicals were sent to the laboratories as coded aliquots from Radian Corporation (Austin, TX). The study chemical was incubated with the *Salmonella typhimurium* tester strains (TA98, TA100, TA1535, and TA1537) either in buffer or S9 mix (metabolic activation enzymes and cofactors from Aroclor 1254-induced male Sprague Dawley rat or Syrian hamster liver) for 20 minutes at 37° C before the addition of soft agar supplemented with L-histidine and D-biotin and subsequent plating on minimal glucose agar plates. Incubation was continued for an additional 48 hours.

Chemicals were tested in four strains. Each test consisted of triplicate plates of concurrent positive and negative controls and of at least five doses of the study chemical. The high dose was limited by toxicity or solubility but did not exceed 10 mg/plate.

A positive response was defined as a reproducible, dose-related increase in histidine-independent (revertant) colonies in any one strain/activation combination. An equivocal response was defined as an increase in revertants which was not dose related, not reproducible, or of insufficient magnitude to support a determination of mutagenicity. A response was considered negative when no increase in revertant colonies was observed after chemical treatment.

Chinese Hamster Ovary Cytogenetics Assays: Testing was performed as reported by Galloway et al. (1985) and is described briefly below. Chemicals were sent to the laboratories as coded aliquots from Radian Corporation (Austin, TX). Chemicals were tested in cultured Chinese hamster ovary (CHO) cells for induction of sister chromatid exchanges (SCEs) and chromosomal aberrations both in the presence and absence of Aroclor 1254-induced male Sprague Dawley rat liver S9 and cofactor mix. Cultures were handled under gold lights to prevent photolysis of bromodeoxyuridine (BrdU)-substituted DNA. Each test consisted of concurrent solvent and positive controls and of at least three doses of the study chemical; the high dose was limited by toxicity or solubility but did not exceed 5 mg/ml.

In the SCE test without S9, CHO cells were incubated for 26 hours with the study chemical in McCoy's 5A medium supplemented with 10% fetal bovine serum, L-glutamine (2 mM), and antibiotics. BrdU was added 2 hours after culture initiation. After 26 hours, the medium containing the study chemical was removed and replaced with fresh medium plus BrdU and colcemid, and incubation was continued for 2 more hours. Cells were then harvested by mitotic shake-off, fixed, and stained with Hoechst 33258 and Giemsa. In the SCE test with S9, cells were incubated with the chemical, serum-free medium, and S9 for 2 hours. The medium was then removed and replaced with medium containing BrdU and no study chemical; incubation proceeded for an additional 26 hours, with colcemid present for the final 2 hours. Harvesting and staining were the same as for cells treated without S9.

In the chromosomal aberration test without S9, cells were incubated in McCoy's 5A medium with the study chemical for 8 hours; colcemid was added, and incubation was continued for 2 hours. The cells were then harvested by mitotic shake-off, fixed, and stained with Giemsa. For the chromosomal aberration test with S9, cells were treated with the study chemical and S9 for 2 hours, after which the treatment medium was removed and the cells were incubated for 10 hours in fresh medium, with colcemid present for the final 2 hours. Cells were harvested in the same manner as for the treatment without S9.

For the SCE test, if significant chemical-induced cell cycle delay was seen, incubation time was lengthened to ensure a sufficient number of scorable cells. The harvest time for the chromosomal aberration test was based on the cell cycle information obtained in the SCE test; if cell cycle delay was anticipated, the incubation period was extended approximately 5 hours.

Cells were selected for scoring on the basis of good morphology and completeness of karyotype (21 ± 2 chromosomes). All slides were scored blind, and those from a single test were read by the same person. For the SCE test, 50 second-division metaphase cells were usually scored for frequency of SCEs per cell from each dose; 200 first-division metaphase cells were scored at each dose for the chromosomal aberration test. Classes of aberrations included simple (breaks and terminal deletions), complex (rearrangements and translocations), and other (pulverized cells, despiralized chromosomes, and cells containing 10 or more aberrations).

Statistical analyses were conducted on both the slopes of the dose-response curves and the individual dose points. An SCE frequency 20% above the concurrent solvent control value was chosen as a statistically conservative positive response. The probability of this level of difference occurring by chance at one dose point is less than 0.01; the probability for such a chance occurrence at two dose points is less than 0.001. Chromosomal aberration data are presented as percentage of cells with aberrations. As with SCEs, both the dose-response curve and individual dose points were statistically analyzed. A statistically significant ($P<0.003$) trend test or a significantly increased dose point ($P<0.05$) was sufficient to indicate a chemical effect.

Drosophila Melanogaster Protocol: The assays for gene mutation and chromosomal translocation induction were performed as described by Yoon et al. (1985). Study chemicals were supplied as coded aliquots from Radian Corporation (Austin, TX). Initially, study chemicals were assayed in the sex-linked recessive lethal (SLRL) test by feeding to adult Canton-S wild-type males that were no more than 24 hours old. If no response was obtained, the chemical was retested by injection into adult males. If either route of administration produced a positive result, the chemical was assayed for induction of reciprocal translocations (RTs) by using the same method of exposure. If, because of the physical nature of the chemical, feeding experiments were not possible, injection was selected as the method of study chemical administration, and a positive result was followed by an RT test.

To administer a chemical by injection, a glass Pasteur pipette is drawn out in a flame to a microfine filament and the tip is broken off to allow delivery of the test solution. Injection is either done manually by attaching a rubber bulb to the other end of the pipette and forcing through sufficient solution to slightly distend the abdomen of the fly (0.2-0.3 µl) or by attaching the pipette to a microinjector that automatically delivers a calibrated volume. Flies are anesthetized with ether and immobilized on a strip of double-stick tape; injection into the thorax under the wing is performed with the aid of a dissecting microscope.

Toxicity tests attempted to set concentrations of study chemical at a level that would produce 30% mortality after 72 hours of feeding or 24 hours after injection, while keeping induced sterility at an acceptable level. For the SLRL test, exposure by feeding was done by allowing Canton-S males (10-20 flies per vial) to feed for 72 hours on a solution of the study chemical in 5% sucrose. In the injection experiments, 24- to 72-hour-old Canton-S males were given a solution of the chemical dissolved in 0.7% saline or peanut oil and allowed 24 hours to recover. Exposed males were mated to three *Basc* females for 3 days and given fresh females at 2-day intervals to produce three matings of 3, 2, and 2 days; sample sperm from successive matings were treated as successively earlier postmeiotic stages. F_1 heterozygous females were allowed to mate with their siblings and then were placed in individual vials. F_1 daughters from the same parental male were kept together to identify clusters. (A cluster occurs when a number of mutants from a given male result from a single spontaneous premeiotic mutation event and is identified when the number of mutants from that male exceeds the number predicted by a Poisson distribution.) If a cluster was identified, all data from the male in question were discarded. After 17 days, presumptive lethal mutations were identified as vials containing no wild-type males; these were retested. At least two experiments were performed for each study chemical, resulting in the testing of some 5,000 treated and 5,000 control chromosomes. The only exceptions occurred when the results of the first experiment were clearly positive (induced frequency of recessive lethal mutations equal to or greater than 1%); then, the second trial was not run.

Recessive lethal data were analyzed by the normal test (Margolin et al., 1983). A test result was considered to be positive if the P value was less than 0.01 and the mutation frequency in the tested group was greater than 0.10% or if the P value was less than 0.05 and the frequency in the treatment group was greater than 0.15%. A test was considered to be inconclusive if (a) the P value was between 0.05 and 0.01 but the frequency in the treatment group was between 0.10% and 0.15% or (b) the P value was between 0.10 and 0.05 but the frequency in the treatment group was greater than 0.10%. A result was considered to be negative if the P value was greater than 0.10 or if the frequency in the treatment group was less than 0.10%.

RESULTS

3,3′-Dimethoxybenzidine was tested for induction of gene mutations in *S. typhimurium* strains TA98, TA100, TA1535, and TA1537 in each of three laboratories (Haworth et al., 1983; Table H1). In all laboratories, a response ranging from weakly positive to positive was observed with strain TA100 in trials conducted in the presence of Aroclor 1254-induced male Sprague Dawley rat or Syrian hamster liver S9; likewise, positive results were reported for strain TA98 with S9 in all three laboratories, and one laboratory also observed a significant response in TA98 without S9. A weakly positive response was reported by one of the test laboratories with TA1535 in the presence of induced hamster S9. In cytogenetic tests with CHO cells conducted in two laboratories, SCEs were induced by 3,3′-dimethoxybenzidine both with and without Aroclor 1254-induced male Sprague Dawley rat liver S9; in one of these two laboratories, the positive responses observed in the SCE trials without S9 occurred under conditions of delayed harvest (3-5 hours additional culture time), but the positive results reported by the second laboratory in the SCE test were observed at lower doses of the study chemical which did not affect cell cycle time (Galloway et al., 1985; Table H2). Results of the chromosomal aberration test were reported to be negative (Galloway et al., 1985); however, recent statistical reanalysis (Galloway et al., 1987) of the chromosomal aberration data has resulted in a change in the call from negative to weakly positive without S9 (Litton Bionetics study) and positive with S9 (Columbia University study) (Table H3). 3,3′-Dimethoxybenzidine was negative for induction of sex-linked recessive lethal mutations in adult male *D. melanogaster* exposed to the chemical by feeding (100 ppm) or injection (200 ppm) (Yoon et al., 1985; Table H4).

TABLE H1. MUTAGENICITY OF 3,3'-DIMETHOXYBENZIDINE IN *SALMONELLA TYPHIMURIUM* (Continued)

(a) The detailed protocol is presented by Haworth et al. (1983). Cells and study compound or solvent (dimethyl sulfoxide) were incubated in the absence of exogenous metabolic activation (−S9) or with Aroclor 1254-induced S9 from male Syrian hamster liver or male Sprague Dawley rat liver. High dose was limited by toxicity or solubility but did not exceed 10 mg/plate; 0 μg/plate dose is the solvent control.
(b) Revertants are presented as mean ± standard error from three plates.
(c) Positive control; 2-aminoanthracene was used on all strains in the presence of S9. In the absence of metabolic activation, 4-nitro-*o*-phenylenediamine was used with TA98, sodium azide was used with TA100 and TA1535, and 9-aminoacridine was used with TA1537.
(d) Precipitate on plate
(e) Slight toxicity

(a) SCE = sister chromatid exchange; BrdU = bromodeoxyuridine. A detailed description of the SCE protocol is presented by Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent as described in (c) and (e) below and cultured for sufficient time to reach second metaphase division. Cells were then collected by mitotic shake-off, fixed, air dried, and stained.
(b) SCEs/cell of culture exposed to study chemical relative to those of culture exposed to solvent
(c) In the absence of S9, Chinese hamster ovary cells were incubated with study compound or solvent for 2 hours at 37° C. Then BrdU was added, and incubation was continued for 24 hours. Cells were washed, fresh medium containing BrdU and colcemid was added, and incubation was continued for 2-3 hours.
(d) Because some chemicals induce a delay in the cell division cycle, harvest times are occasionally extended to maximize the proportion of second division cells available for analysis.
(e) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37° C. Cells were then washed, and medium containing BrdU was added. Cells were incubated for a further 26 hours, with colcemid present for the final 2-3 hours. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

TABLE H3. INDUCTION OF CHROMOSOMAL ABERRATIONS IN CHINESE HAMSTER OVARY CELLS BY 3,3'-DIMETHOXYBENZIDINE (Continued)

(a) Abs = aberrations. A detailed presentation of the technique for detecting chromosomal aberrations is found in Galloway et al. (1985). Briefly, Chinese hamster ovary cells were incubated with study compound or solvent as indicated in (b) and (c). Cells were arrested in first metaphase by addition of colcemid and harvested by mitotic shake-off, fixed, and stained in 6% Giemsa.
(b) In the absence of S9, cells were incubated with study compound or solvent for 8-10 hours at 37° C. Cells were then washed, and fresh medium containing colcemid was added for an additional 2-3 hours followed by harvest.
(c) In the presence of S9, cells were incubated with study compound or solvent for 2 hours at 37° C. Cells were then washed, medium was added, and incubation was continued for 8-10 hours. Colcemid was added for the last 2-3 hours of incubation before harvest. S9 was from the liver of Aroclor 1254-induced male Sprague Dawley rats.

TABLE H4. INDUCTION OF SEX-LINKED RECESSIVE LETHAL MUTATIONS IN *DROSOPHILA MELANOGASTER* BY 3,3'-DIMETHOXYBENZIDINE (a)

Route of Exposure	Dose (ppm)	Incidence of Deaths (percent)	Incidence of Sterility (percent)	No. of Lethals/No. of X Chromosomes Tested Mating 1	Mating 2	Mating 3	Overall Total (b)
Feeding	100	0	0	2/2,295	1/2,266	0/2,191	3/6,752 (0.04%)
	0			1/3,410	1/3,375	1/3,127	3/9,912 (0.03%)
Injection	200	0	0	0/1,700	0/1,570	0/1,481	0/4,751 (0.00%)
	0			0/1,360	2/1,291	0/1,213	2/3,864 (0.05%)

(a) Study performed at the University of Wisconsin–Madison. A detailed protocol of the sex-linked recessive lethal assay and data are presented by Yoon et al. (1985). Exposure by feeding was done by allowing 24-hour-old Canton-S males to feed for 3 days on a solution of the study chemical dissolved in 5% sucrose. In the injection experiments, 24-hour-old Canton-S males were treated with a solution of the chemical dissolved in 0.7% saline and allowed 24 hours to recover. Exposed males were mated to three *Basc* females for 3 days and given fresh females at 2-day intervals to produce three broods of 3, 2, and 2 days; sample sperm from successive matings were treated as spermatozoa (mating 1), spermatids (mating 2), and spermatocytes (mating 3). F_1 heterozygous females were crossed to their siblings and placed in individual vials. F_1 daughters from the same parental male were kept together to identify clusters; no clusters were found. After 17 days, presumptive lethal mutations were identified as vials containing no wild-type males; these were retested. Results were not significant at the 5% level (Margolin et al., 1983).
(b) Combined total of number of lethal mutations/number of X chromosomes tested for three mating trials

APPENDIX I

AUDIT SUMMARY

APPENDIX I. AUDIT SUMMARY

The pathology specimens, experimental data, study documents, and draft NTP Technical Report for the 2-year studies of 3,3'-dimethoxybenzidine dihydrochloride in rats were audited for the National Institute of Environmental Health Sciences (NIEHS) at the National Toxicology Program (NTP) Archives by quality assurance, resource-support contractors. The audit included review of:

(1) All records concerning animal receipt, quarantine, randomization, and disposition prior to study start.
(2) All inlife records including protocol, correspondence, animal husbandry, environmental conditions, dosing, animal identification, external masses, mortality, and serology.
(3) Body weight and clinical observation data; all data were scanned before individual data for a random 10% sample of animals in each study group were reviewed in detail.
(4) All chemistry records.
(5) All postmortem records for individual animals concerning date of death, disposition code, condition code, tissue accountability, correlation of masses or clinical signs recorded at or near the last inlife observation with gross observations and microscopic diagnoses, consis-tency of data entry on necropsy record forms, and correlation between gross observations and microscopic diagnoses.
(6) All wet tissue bags for inventory and residual wet tissues from a random 20% sample of animals in each study group, plus other relevant cases, to evaluate the integrity of individual animal identity and the thoroughness of necropsy and trimming procedure performance.
(7) Blocks and slides of tissues from a random 20% sample of animals from each study group, plus animals with less than complete or correct identification, to examine for proper inventory, labeling, matching of tissue sections, and preservation.
(8) All microscopic diagnoses for a random 10% sample of animals, plus 100% of the changes in diagnoses made to preliminary pathology tables, to verify their incorporation into the final pathology tables.
(9) The extent of correlation between the data, factual information, and procedures for the 2-year studies as presented in the draft Technical Report and the study records available at the NTP Archives.

Procedures and events for the exposure phase of the studies were documented adequately by the archival records, with the exception that some or all of the records for room air change rate, room light cycle, source of bedding and cages, study chemical receipt and disposal, original chemistry notebook pages, and statistical analysis of some primary tumors were not present. Review of the records indicated that protocol-specified procedures for animal care were followed adequately. Records that documented the administration of doses to animals were complete and accurate. Recalculation of approximately 20% of the group mean body weight values in the Technical Report showed 30/31 to be correct. Review of water consumption records detected a few data entry errors of small magnitude. The correlation between observations of external masses recorded both during the last few months of life and at necropsy was good (785/799 correlated). The date of animal removal correlated with the date of necropsy for all 362 early-death animals. The reason for animal removal recorded during life correlated with the disposition code recorded at necropsy for each rat.

Individual animal identifiers (ear tags) were present and correct in the residual-tissue bags for 80/81 rats examined. Review of the entire data trail for the one rat with an incorrect identifier indicated that the integrity of individual animal identity had been maintained. The audit detected 17 untrimmed potential lesions among the wet tissues of 56 rats examined. Additional histopathology work on the residual livers of all study animals by a pathology-support contractor detected 76 untrimmed lesions, which, when evaluated, resulted in the diagnosis of 7 neoplasms in male rats which had not been identified previously, no additional neoplasms in female rats, and about 30 new nonneoplastic lesions in male and female rats. The additional diagnoses were not incorporated into the tables of the Technical Report; the missing neoplastic diagnoses included nodules in the liver of one control (CM61), one low dose (LM167), and one high dose (HM424) male rats; adenocarcinomas in the colon of one low dose (LM171) and two mid dose (MM231 and MM284) male rats; and an adenometous polyp in one mid dose (MM245, multiple) male rat.

Intestinal segments were incompletely opened for 8/25 rats; however, there were no apparent untrimmed potential lesions evident by external examination of residual tissues for the gastrointestinal tract. Twenty-seven gross observations made at necropsy did not have a corresponding microscopic diagnosis. Tissue sections on blocks and slides matched each other properly. All but two post-Pathology Working Group changes in diagnoses had been incorporated into the final pathology tables.

Full details about these and other findings are presented in audit reports that are on file at NIEHS. This summary describes the extent to which the data and factual information presented in the Technical Report are supported by records at the NTP Archives.
