FOREWORD

The National Toxicology Program (NTP) is made up of four charter agencies of the U.S. Department of Health and Human Services (DHHS): the National Cancer Institute (NCI), National Institutes of Health; the National Institute of Environmental Health Sciences (NIEHS), National Institutes of Health; the National Center for Toxicological Research (NCTR), Food and Drug Administration; and the National Institute for Occupational Safety and Health (NIOSH), Centers for Disease Control. In July 1981, the Carcinogenesis Bioassay Testing Program, NCI, was transferred to the NIEHS. The NTP coordinates the relevant programs, staff, and resources from these Public Health Service agencies relating to basic and applied research and to biological assay development and validation.

The NTP develops, evaluates, and disseminates scientific information about potentially toxic and hazardous chemicals. This knowledge is used for protecting the health of the American people and for the primary prevention of disease.

The studies described in this Technical Report were performed under the direction of the NIEHS and were conducted in compliance with NTP laboratory health and safety requirements and must meet or exceed all applicable federal, state, and local health and safety regulations. Animal care and use were in accordance with the Public Health Service Policy on Humane Care and Use of Animals. The prechronic and chronic studies were conducted in compliance with Food and Drug Administration (FDA) Good Laboratory Practice Regulations, and all aspects of the chronic studies were subjected to retrospective quality assurance audits before being presented for public review.

These studies are designed and conducted to characterize and evaluate the toxicologic potential, including carcinogenic activity, of selected chemicals in laboratory animals (usually two species, rats and mice). Chemicals selected for NTP toxicology and carcinogenesis studies are chosen primarily on the bases of human exposure, level of production, and chemical structure. Selection *per se* is not an indicator of a chemical's carcinogenic potential.

These NTP Technical Reports are available for sale from the National Technical Information Service, U.S. Department of Commerce, 5285 Port Royal Road, Springfield, VA 22161 (703-487-4650). Single copies of this Technical Report are available without charge while supplies last from NTP Central Data Management, NIEHS, P.O. Box 12233, MD A0-01, Research Triangle Park, NC 27709 (919-541-1371).

ABSTRACT

O_3

OZONE

CAS No. 10028-15-6

Chemical Formula: O_3 Molecular Weight: 48

Synonym: Triatomic oxygen

There is widespread concern over the health effects of oxidant air pollutants. The state of California and the Health Effects Institute (HEI) (a nonprofit research institute funded jointly by the U.S. Environmental Protection Agency [USEPA] and combustion engine manufacturers) nominated ozone for evaluation in long-term animal studies. The NTP study designs were a result of a series of meetings at the NIEHS with scientists from NIEHS, USEPA, and HEI, as well as experts from academic institutions working in the area of air pollutants. Male and female F344/N rats and B6C3F$_1$ mice were exposed to ozone by inhalation for 4 weeks, 2 years, or for 124 weeks (rats) or 130 weeks (mice). The oxygen used to generate the ozone was greater than 99.9% pure. Additional groups of male F344/N rats were administered injections of 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) (≥ 99% pure) 3 times per week for 20 weeks and exposed to ozone by inhalation for 2 years. Genetic toxicology studies were conducted in *Salmonella typhimurium*.

4-Week Ozone Study in Rats

Groups of five male and five female F344/N rats were exposed to 0, 0.5, or 1.0 ppm ozone by inhalation 6 hours per day, 5 days per week, for a total of 20 days. All rats survived to the end of the study. The final mean body weights and mean body weight gains of 0.5 ppm males and females and of 1.0 ppm females were similar to those of the controls. The final mean body weight of 1.0 ppm males was 7% lower than that of the controls. Clinical findings included hypoactivity in 1.0 ppm males and females and ruffled fur in exposed groups of males.

Male and female rats exposed to 0.5 or 1.0 ppm developed multifocal lesions of the lung, which consisted of infiltration of granulocytes and macrophages with extension of the bronchial epithelium into the alveolar ducts. Female rats exposed to ozone developed minimal squamous metaplasia of the laryngeal epithelium at the base of the epiglottis.

Absolute and relative lung weights of all exposed groups of males and females were greater than those of the controls, and absolute and relative thymus weights of all exposed groups were generally lower than those of the controls.

4-Week Ozone Study in Mice

Groups of five male and five female B6C3F$_1$ mice were exposed to 0, 0.5, or 1.0 ppm ozone by inhalation 6 hours per day, 5 days per week, for a total of 20 days. All mice survived to the end of the study. The final mean body weights and body weight gains of all exposed groups of mice were less than those of the controls. Hypoactivity was observed in 1.0 ppm mice.

Male and female mice exposed to 0.5 or 1.0 ppm ozone developed patchy, multifocal lesions of the lung, which consisted of infiltration of granulocytes

and macrophages with extension of the bronchial epithelium into the alveolar ducts.

The relative lung weight of 1.0 ppm males was significantly greater than that of the controls. There were no other statistically significant differences in absolute or relative organ weights in males or females.

2-Year Ozone Study in Rats

The 2-year study was designed to include the present USEPA standard (0.12 ppm), the maximum concentration believed compatible with long-term survival (1.0 ppm), and an intermediate concentration (0.5 ppm). Groups of 50 male and 50 female F344/N rats were exposed to 0, 0.12, 0.5, or 1.0 ppm ozone by inhalation for 6 hours per day, 5 days per week, for 105 weeks.

Survival, Body Weights, and Clinical Findings

Survival of exposed groups of rats was similar to that of the controls at the end of the study. The mean body weights of 0.12 and 0.5 ppm males and females were similar to those of the controls throughout the study. The mean body weights of 1.0 ppm males and females were slightly lower than those of the controls throughout the study. Hypoactivity was observed in male and female rats exposed to ozone.

Pathology Findings

Increased incidences of ozone-induced metaplasia occurred in the nose and lung of rats exposed to 0.5 or 1.0 ppm ozone. The lesions in the nose were characterized by an increase in the number of goblet cells in the respiratory epithelium with mild squamous metaplasia of the cuboidal epithelium on the lateral wall. The increase in the number of goblet cells was found primarily in level I and II epithelium occurring along the lateral wall and on the maxilloturbinates and nasoturbinates. The metaplasia in the lung was a patchy multifocal lesion consisting of extension of the bronchial epithelium into the alveoli of the centriacinar region. This may represent more an extension of the bronchial epithelium into the pulmonary parenchyma than an actual transition of one epithelial cell type into another. There were increased incidences of squamous metaplasia at the base of the epiglottis characterized by one or more layers of flattened epithelial cells where low cuboidal cells are normally found.

There were no increases in the incidences of alveolar/bronchiolar adenoma or carcinoma in either males or females exposed to ozone.

Lifetime Ozone Study in Rats

For this study, rats were exposed to 0.5 and 1.0 ppm ozone for an additional 6 months to determine the effect of extended exposure on neoplasm incidence. Groups of 50 male and 50 female F344/N rats were exposed to 0, 0.5, or 1.0 ppm ozone by inhalation for 6 hours per day, 5 days per week, for 125 weeks.

Survival, Body Weights, and Clinical Findings

Survival rates of exposed rats were similar to those of the controls. The mean body weights of 0.5 ppm males and females were similar to those of the controls throughout the study. The mean body weights of 1.0 ppm males and females were slightly lower than those of the controls for the first two years of the study. Hypoactivity was observed in exposed groups of males and females.

Pathology Findings

Increased incidences of metaplasia occurred in the nose, larynx, and lung of rats exposed to 0.5 or 1.0 ppm ozone. The lung lesions were multifocal, centriacinar and were characterized by the presence of cuboidal epithelium (ciliated and nonciliated) along the alveolar ducts where type I epithelium is normally present. Inflammation (histiocytic infiltration) and interstitial fibrosis were observed in the lung of exposed males and females, and hyperplasia was observed in the nose of exposed male and female groups. There were no ozone-related increased incidences of neoplasms.

2-Year Ozone/NNK Study in Male Rats

An intermediate concentration of 0.5 ppm ozone was combined with exposure to two levels of a known carcinogen (0.1 and 1.0 mg NNK/kg body weight) in order to determine if ozone promotes the carcinogenic process or acts as a cocarcinogen. Groups of 48 male F344/N rats were exposed to 0 or 0.5 ppm ozone by inhalation, 6 hours per day, 5 days per week for 105 weeks. During the first 20 weeks of the study, these rats were subcutaneously injected with 0, 0.1, or 1.0 mg NNK per kg body weight in trioctanoin three times weekly.

Survival and Body Weights

Two-year survival rates of male rats were similar in all groups. Final mean body weights of all males exposed to NNK alone or NNK and ozone were similar to that of the controls, with the exception of rats exposed to 1.0 mg NNK/kg body weight and 0.5 ppm ozone. Hypoactivity was observed in males exposed to NNK and ozone, in those exposed to NNK without ozone, and in those exposed to ozone only.

Pathology Findings

Alveolar epithelial metaplasia and interstitial fibrosis occurred in all groups of rats exposed to ozone or to NNK and ozone, but not in those exposed to NNK without ozone. Increased incidences of hyperplasia occurred in groups of rats exposed to NNK or to ozone and NNK. Incidences of hyperplasia were similar among groups of rats exposed to NNK only. An increased incidence of alveolar/bronchiolar adenoma or carcinoma (combined) occurred in rats administered 1.0 mg/kg NNK, with or without ozone. The administration of ozone did not affect the occurrence of pulmonary neoplasms or nonneoplastic lesions in rats administered NNK.

2-YEAR OZONE STUDY IN MICE

The 2-year study was designed to include the present USEPA standard (0.12 ppm), the maximum concentration believed compatible with long-term survival (1.0 ppm), and an intermediate concentration (0.5 ppm). Groups of 50 male and 50 female B6C3F$_1$ mice were exposed to 0, 0.12, 0.5, or 1.0 ppm ozone by inhalation for 6 hours per day, 5 days per week, for 105 weeks.

Survival, Body Weights, and Clinical Findings

Survival rates of exposed mice were generally similar to those of the controls; the 2-year survival rate of 1.0 ppm females was greater than that of the controls. The mean body weights of 0.12 and 0.5 ppm males were similar to that of the controls throughout the study; the mean body weights of 1.0 ppm males and of all exposed groups of females were generally lower than those of the controls throughout the study. Hypoactivity was observed in male and female mice exposed to ozone.

Pathology Findings

Increased incidences of metaplasia occurred in the nose and lung of mice exposed to 0.5 or 1.0 ppm ozone. The metaplasia in the nose consisted of increased thickening and extension of the squamous epithelium in the anterior portion of the nasal passage. The metaplasia in the lung consisted of extension of the bronchial epithelium into the alveoli of the centriacinar region. There were increased incidences of hyperplasia in the nose characterized by thickening of the noncuboidal (transitional) epithelium. There were increased incidences of hyperplasia in the epiglottis of female mice, a change that was characterized by a minimal increase in the thickness of the epithelium.

Incidences of alveolar/bronchiolar adenoma or carcinoma (combined) were marginally increased in 0.5 and 1.0 ppm males (0 ppm, 14/50; 0.12 ppm, 13/50; 0.5 ppm, 18/50; 1.0 ppm, 19/50) and were increased in 1.0 ppm females (6/50, 7/50, 9/49, 16/50).

LIFETIME OZONE STUDY IN MICE

For this study, mice were exposed to 0.5 and 1.0 ppm ozone for 30 months to determine the effect of extended exposure on neoplasm incidence. Groups of 50 male and 50 female B6C3F$_1$ mice were exposed to 0, 0.5, or 1.0 ppm ozone by inhalation for 6 hours per day, 5 days per week, for 130 weeks.

Survival and Body Weights

Survival rates of exposed mice were similar to those of the controls. The mean body weights of 0.5 ppm males and females were similar to those of the controls throughout the study. The mean body weights of 1.0 ppm males and females were generally lower than those of the controls throughout the study. Hypoactivity was observed in male and female mice exposed to ozone.

Pathology Findings

The incidences of alveolar/bronchiolar adenoma and carcinoma (combined) were marginally increased in exposed males (0 ppm, 16/49; 0.5 ppm, 22/49; 1.0 ppm, 21/50) and in exposed females (6/50, 8/49, 12/50).

Increased incidences of metaplasia occurred in the nose, larynx, and lung of exposed groups of males and females, and the incidences of hyperplasia were increased in the larynx and nose of exposed mice. The morphology of the lesions was similar to that seen in the 2-year study. There were no ozone-related increases in alveolar epithelial hyperplasia.

GENETIC TOXICOLOGY

Ozone was mutagenic in *Salmonella typhimurium* strain TA102, with and without S9 metabolic activation.

CONCLUSIONS

Under the conditions of these 2-year and lifetime inhalation studies, there was *no evidence of carcinogenic activity** of ozone in male or female F344/N rats exposed to 0.12, 0.5, or 1.0 ppm. There was *equivocal evidence of carcinogenic activity* of ozone in male $B6C3F_1$ mice based on increased incidences of alveolar/bronchiolar adenoma or carcinoma. There was *some evidence of carcinogenic activity* of ozone in female $B6C3F_1$ mice based on increased incidences of alveolar/bronchiolar adenoma or carcinoma.

There was no evidence that exposure to 0.5 ppm ozone enhanced the incidence of NNK-induced pulmonary neoplasms in male rats.

Exposure of male and female rats to ozone for 2 years or 125 weeks was associated with goblet cell hyperplasia and squamous metaplasia in the nose, squamous metaplasia in the larynx, and metaplasia (extension of bronchial epithelium into the centriacinar alveolar ducts) and interstitial fibrosis in the lung. Exposure of male and female mice to ozone for 2 years or 130 weeks was associated with hyperplasia and squamous metaplasia in the nose and inflammation (histiocytic infiltration) and metaplasia (extension of bronchial epithelium into the centriacinar alveolar ducts) of the lung.

---

* Explanation of Levels of Evidence of Carcinogenic Activity is on page 11. A summary of the Technical Reports Review Subcommittee comments and the public discussion on this Technical Report appears on page 13.

Summary of the 2-Year and Lifetime Carcinogenesis and Genetic Toxicology Studies of Ozone

	Male F344/N Rats 2-Year Study	Male F344/N Rats Lifetime Study	Female F344/N Rats 2-Year Study	Female F344/N Rats Lifetime Study
Doses	0, 0.12, 0.5, or 1.0 ppm by inhalation	0, 0.5, or 1.0 ppm by inhalation	0, 0.12, 0.5, or 1.0 ppm by inhalation	0, 0.5, or 1.0 ppm by inhalation
Body weights	1.0 ppm group slightly lower than controls	1.0 ppm group lower than controls	1.0 ppm group slightly lower than controls	1.0 ppm group slightly lower than controls

EXPLANATION OF LEVELS OF EVIDENCE OF CARCINOGENIC ACTIVITY

The National Toxicology Program describes the results of individual experiments on a chemical agent and notes the strength of the evidence for conclusions regarding each study. Negative results, in which the study animals do not have a greater incidence of neoplasia than control animals, do not necessarily mean that a chemical is not a carcinogen, inasmuch as the experiments are conducted under a limited set of conditions. Positive results demonstrate that a chemical is carcinogenic for laboratory animals under the conditions of the study and indicate that exposure to the chemical has the potential for hazard to humans. Other organizations, such as the International Agency for Research on Cancer, assign a strength of evidence for conclusions based on an examination of all available evidence, including animal studies such as those conducted by the NTP, epidemiologic studies, and estimates of exposure. Thus, the actual determination of risk to humans from chemicals found to be carcinogenic in laboratory animals requires a wider analysis that extends beyond the purview of these studies.

Five categories of evidence of carcinogenic activity are used in the Technical Report series to summarize the strength of the evidence observed in each experiment: two categories for positive results (**clear evidence** and **some evidence**); one category for uncertain findings (**equivocal evidence**); one category for no observable effects (**no evidence**); and one category for experiments that cannot be evaluated because of major flaws (**inadequate study**). These categories of interpretative conclusions were first adopted in June 1983 and then revised in March 1986 for use in the Technical Report series to incorporate more specifically the concept of actual weight of evidence of carcinogenic activity. For each separate experiment (male rats, female rats, male mice, female mice), one of the following five categories is selected to describe the findings. These categories refer to the strength of the experimental evidence and not to potency or mechanism.

- **Clear evidence** of carcinogenic activity is demonstrated by studies that are interpreted as showing a dose-related (i) increase of malignant neoplasms, (ii) increase of a combination of malignant and benign neoplasms, or (iii) marked increase of benign neoplasms if there is an indication from this or other studies of the ability of such tumors to progress to malignancy.
- **Some evidence** of carcinogenic activity is demonstrated by studies that are interpreted as showing a chemical-related increased incidence of neoplasms (malignant, benign, or combined) in which the strength of the response is less than that required for clear evidence.
- **Equivocal evidence** of carcinogenic activity is demonstrated by studies that are interpreted as showing a marginal increase of neoplasms that may be chemical related.
- **No evidence** of carcinogenic activity is demonstrated by studies that are interpreted as showing no chemical-related increases in malignant or benign neoplasms.
- **Inadequate study** of carcinogenic activity is demonstrated by studies that, because of major qualitative or quantitative limitations, cannot be interpreted as valid for showing either the presence or absence of carcinogenic activity.

When a conclusion statement for a particular experiment is selected, consideration must be given to key factors that would extend the actual boundary of an individual category of evidence. Such consideration should allow for incorporation of scientific experience and current understanding of long-term carcinogenesis studies in laboratory animals, especially for those evaluations that may be on the borderline between two adjacent levels. These considerations should include:

- adequacy of the experimental design and conduct;
- occurrence of common versus uncommon neoplasia;
- progression (or lack thereof) from benign to malignant neoplasia as well as from preneoplastic to neoplastic lesions;
- some benign neoplasms have the capacity to regress but others (of the same morphologic type) progress. At present, it is impossible to identify the difference. Therefore, where progression is known to be a possibility, the most prudent course is to assume that benign neoplasms of those types have the potential to become malignant;
- combining benign and malignant tumor incidence known or thought to represent stages of progression in the same organ or tissue;
- latency in tumor induction;
- multiplicity in site-specific neoplasia;
- metastases;
- supporting information from proliferative lesions (hyperplasia) in the same site of neoplasia or in other experiments (same lesion in another sex or species);
- presence or absence of dose relationships;
- statistical significance of the observed tumor increase;
- concurrent control tumor incidence as well as the historical control rate and variability for a specific neoplasm;
- survival-adjusted analyses and false positive or false negative concerns;
- structure-activity correlations; and
- in some cases, genetic toxicology.

NATIONAL TOXICOLOGY PROGRAM BOARD OF SCIENTIFIC COUNSELORS
TECHNICAL REPORTS REVIEW SUBCOMMITTEE

The members of the Technical Reports Review Subcommittee who evaluated the draft NTP Technical Report on Ozone and Ozone/NNK on November 16, 1993, are listed below. Subcommittee members serve as independent scientists, not as representatives of any institution, company, or governmental agency. In this capacity, subcommittee members have five major responsibilities in reviewing NTP studies:

- to ascertain that all relevant literature data have been adequately cited and interpreted,
- to determine if the design and conditions of the NTP studies were appropriate,
- to ensure that the Technical Report presents the experimental results and conclusions fully and clearly,
- to judge the significance of the experimental results by scientific criteria, and
- to assess the evaluation of the evidence of carcinogenic activity and other observed toxic responses.

SUMMARY OF TECHNICAL REPORTS REVIEW SUBCOMMITTEE COMMENTS

On November 16, 1993, the draft Technical Report on the toxicology and carcinogenesis studies of ozone and ozone/NNK received public review by the National Toxicology Program Board of Scientific Counselors Technical Reports Review Subcommittee. The review meeting was held at the National Institute of Environmental Health Sciences, Research Triangle Park, NC.

Dr. G.A. Boorman, NIEHS, introduced the toxicology and carcinogenesis studies of ozone and ozone/NNK by discussing the four basic studies: (1) 4-week studies in rats and mice; (2) the standard 2-year studies in rats and mice; (3) 30-month studies in rats and mice; and (4) a 2-year cocarcinogenesis or promotion study in male rats with NNK, a known carcinogen and tobacco-specific nitrosamine. He reported on survival and body weight effects and commented on the lack of neoplastic effects in male and female rats in the 2-year and 30-month studies and on compound-related neoplastic lesions in male and female mice in the 2-year and 30-month studies. Dr. Boorman discussed factors supporting or arguing against a compound-related carcinogenic effect in male and female mice. The proposed conclusions for the studies were: *no evidence of carcinogenic activity* of ozone in male and female F/344N rats; *equivocal evidence of carcinogenic activity* of ozone in male $B6C3F_1$ mice; and *some evidence of carcinogenic activity* of ozone in female $B6C3F_1$ mice.

Dr. van Zwieten, a principal reviewer, agreed with the proposed conclusions. He suggested that the Abstract should summarize pathology findings from the 4-week studies. He added that since the report documents a comprehensive series of studies with ozone, consideration should be given to including photomicrographs of ozone-induced lesions in the respiratory tract of rodents. Dr. Boorman agreed.

Dr. Bailey, the second principal reviewer, agreed with the proposed conclusions. He said the report indicated that "hypoactivity was observed in male and female rats exposed to ozone" and asked when the hypoactivity was seen. Dr. Boorman indicated that this occurred only during exposure and immediately afterwards.

Dr. Taylor, the third principal reviewer, stated that prior to the meeting he thought *equivocal evidence of carcinogenic activity* was more appropriate for female mice based on the relatively flat dose-response curve in the lifetime ozone studies. However, after looking at the combined data from the 2-year and lifetime studies, he supported the proposed conclusions in the report for female mice as well as the other proposed conclusions. Dr. J.K. Haseman, NIEHS, said there were two primary factors supporting *some evidence of carcinogenic activity* in female mice. One was that in the 2-year study there were 16 animals with alveolar/bronchiolar adenoma or carcinoma in the female 1.0 ppm group; this incidence was more than double the maximum seen historically in inhalation study controls. Second, in the analyses of the 2-year and lifetime studies (combined), the trend and the 1 ppm effects were an order of magnitude more significant in female mice than in male mice.

Dr. Ward questioned combining the conclusions in mice particularly since the incidence of alveolar/bronchiolar adenoma or carcinoma was higher in the 2-year study than in the lifetime study. Dr. Haseman responded that the combined analyses have the advantage of using all of the data, and because survival adjusted methods are used, animals are being compared to animals of equivalent age. Dr. Y. Vostal, Environmental Health Consultants, commented that a statement in the Introduction indicating that the primary source of ozone in urban areas was automotive emissions was incorrect.

Dr. van Zwieten moved that the Technical Report on ozone and ozone/NNK be accepted with the revisions discussed and with the conclusions that there was *no evidence of carcinogenic activity* for male and female rats, *equivocal evidence of carcinogenic activity* for male mice, and *some evidence of carcinogenic activity* for female mice. Dr. Taylor seconded the motion, which was accepted by four yes votes with one abstention (Dr. Ryan).

INTRODUCTION

O_3

OZONE

CAS No. 10028-15-6

Chemical Formula: O_3 Molecular Weight: 48

Synonym: Triatomic oxygen

CHEMICAL AND PHYSICAL PROPERTIES

Ozone is a highly reactive, bluish gas with a slightly pungent odor (*Patty's Industrial Hygiene and Toxicology*, 1985). The material is highly unstable with a melting point of −192° C and a boiling point of −112° C. Ozone is approximately 1.6 times heavier than air (*Hawley's Condensed Chemical Dictionary*, 1987).

USE AND HUMAN EXPOSURE

Ozone has been used commercially as an effective disinfectant in the treatment of wastewater, as an odor control compound for waste odors and around sewage-treatment plants, and as a disinfectant in swimming pools. Ozone is also used to bleach paper pulp and cotton fibers (Welsbach, 1980).

Ozone is the major oxidizing component in the type of air pollution known as photochemical smog. It is a highly reactive, unstable triatomic molecule that is formed naturally in the stratosphere by photodissociation of oxygen. Because the gas is very unstable and is rapidly destroyed when it reacts with components in the lower atmosphere, concentrations of ozone at ground level are usually less than 0.1 ppm. However, when ultraviolet solar radiation interacts with atmospheric pollutants (i.e., oxides of nitrogen, olefinic hydrocarbons, and aldehydes) ozone can be formed in the lower atmosphere and can contribute to the oxidant potential of polluted air. Concentrations of ozone in the lower atmosphere are variable and depend on a number of factors, including geographic location, time of year, meteorological conditions, concentrations of reactants, and the degree of activation by sunlight. In highly populated areas such as Los Angeles, CA, where particularly favorable conditions exist for the generation of atmospheric ozone, concentrations as high as 1.0 ppm have been recorded. Concentrations ranging between 0.2 and 0.5 ppm occur frequently during summer months. The U.S. Environmental Protection Agency (USEPA) standard is 0.12 ppm. The standard is attained when the expected number of days per year with maximum hourly average concentrations above 0.12 ppm is equal to or less than one (40 CFR, Part 50). Due to control efforts, the ozone concentrations in many major cities have decreased over the past 20 years, and levels above 0.5 ppm are uncommon. However, the USEPA currently estimates that more than 115 million people in the U.S. are exposed to ozone levels exceeding the USEPA standard each year (USEPA, 1986).

ABSORPTION, DISTRIBUTION, METABOLISM, AND EXCRETION

Because of the thickness and nature of the fluid lining the airways of the lung, little, if any, ozone diffuses through the air-blood interface intact. Therefore, while absorption of ozone is an important consideration, metabolism and excretion are less important concerns in ozone toxicity.

Experimental Animals

Absorption of ozone in the respiratory system depends on the morphology of the respiratory tract, oral versus oronasal breathing, depth and rate of breathing, and properties of the fluids lining the airway. Because most ozone toxicity is believed to be related to the reactive products formed by absorbed ozone, the rate of absorption and the location and thickness of the lining fluid layer is important. Dosimetric ozone studies have been summarized in an ozone criteria document (USEPA, 1986). Nasopharyngeal absorption may be particularly important in obligatory nose breathers, and this factor should be taken into account when comparing ozone toxicity in experimental animals and humans. In a study of absorption in the upper respiratory tract, Yokoyama and Frank (1972) reported a 72% ozone uptake in the nasopharynx of beagle dogs. In the lower respiratory tract, the tissue concentration is highest in the terminal bronchioles, where the mucus blanket lining the airway ends. The tissue concentration decreases rapidly distally from this location and is very low in the trachea (Miller *et al.*, 1985, 1993; Overton and Graham, 1989; Grotberg, 1990; Hu *et al.*, 1992). In both experimental animals and humans, exercise increases the dose to the centriacinar region (Miller *et al.*, 1985; Grotberg, 1990). Because ozone is highly reactive, most of it reacts with the lung lining fluid layer; there are virtually no experimental data on how deep ozone can penetrate into the lung tissue (Pryor, 1992), but it can cause peroxidation of cellular polyunsaturated fatty acids.

Humans

Most of the absorption studies in humans have used measurements of the removal of ozone from inspired air. Ozone levels were measured in a study of healthy, young, nonsmoking male volunteers, breathing through their noses only, their mouths only, or oronasally (Gerrity *et al.*, 1988). The mean extrathoracic removal efficiency was 40% and mean intrathoracic removal efficiency was 91%, suggesting that nearly all of the inspired ozone is adsorbed or reacts with lining fluids in the nasal cavity and air passages. There was a 10% greater ozone uptake by oral breathing than by nasal breathing, suggesting that oral or oronasal breathing does not pose a greater risk. Other studies have confirmed this observation (Hynes *et al.*, 1988; Adams *et al.*, 1989).

TOXICITY IN THE RESPIRATORY TRACT

Experimental Animals

The biochemical basis of ozone toxicity is not yet fully understood. Most of the toxicity is believed to be related to the ozone reaction products, including free radicals, aldehydes, hydrogen peroxide, and ozonides (Lai *et al.*, 1990; Mustafa, 1990; Pryor *et al.*, 1991). A significant portion of ozone reacts with the lipids lining the lung, and ozone will penetrate to tissues only where the fluid lining is thinner than 0.1 μm; these issues confound the determination of a relevant dose of ozone and how best to estimate total dose. There are also a variety of antioxidants that appear to protect cells from the toxic effects of ozone, including the dietary level of vitamin E (Elsayed *et al.*, 1988) and tissue glutathione levels (Boehme *et al.*, 1992); these protective mechanisms are important in evaluating the toxicity of ozone.

The LD_{50} for mice and rats exposed to ozone for 3 hours appears to be about 20 ppm (Mittler *et al.*, 1956). However, there is a four-fold increase in pulmonary lavage fluid protein in rats and mice exposed to as little as 2 ppm ozone for 4 hours (Hatch *et al.*, 1986), suggesting that exposure to 2 ppm may not be compatible with long-term survival. The cause of death in animals exposed to higher ozone concentrations appears to be related to cell death, increased permeability, and pulmonary edema. Most of the recent studies have used lower concentrations of ozone that more closely parallel levels in the environment.

The literature on the short-term toxicity of ozone is extensive and has been summarized in the most recent ozone criteria document (USEPA, 1986). All mammalian species studied react to inhaled ozone in a generally similar manner, with species variations due to physiological and structural differences of the respiratory tract. Ozone damage occurs in rodents along the entire respiratory tract, but is most severe in the terminal bronchioles (Dungworth *et al.*, 1975). Damage varies among different centriacinar regions in a single rat (Schwartz *et al.*, 1976; Boorman *et al.*, 1980). It has been shown that the severity of the damage depends on the distance of the centriacinar region from the trachea. Following acute ozone exposure in rodents and monkeys, pulmonary changes

are characterized by inflammation, increased protein in the bronchoalveolar fluid, degeneration and necrosis of airway lining cells, and increased thickness of the alveolar septa (Castleman *et al.*, 1980; Crapo *et al.*, 1984). Most of the emphasis has focused on the centriacinar region of the lung, the most sensitive site for ozone-induced toxicity. Exposure to as little as 0.1 ppm ozone is associated with flattening of the Clara cells, loss of cilia in the terminal bronchioles, and an influx of granulocytes and alveolar macrophages with a reorganization of the epithelium of the airways (Boorman *et al.*, 1980; Moore and Schwartz, 1981). Bronchiolization is also reported in nonhuman primates exposed to 0.64 ppm ozone for 1 year (Eustis *et al.*, 1981; Fujinaka *et al.*, 1985). With continued exposure, much of the inflammatory response subsides, suggesting an adaptive response to continued exposure (Schwartz *et al.*, 1976).

Ozone exposure causes alterations in the nasopharynx, larynx, and trachea. In the nasopharynx/respiratory epithelium of bonnet monkeys, there is loss of cilia and necrosis of ciliated cells (Harkema *et al.*, 1987). In rats, ozone also causes an increase in proliferation of the nonciliated epithelial cells (Johnson *et al.*, 1990).

The literature on the long-term toxicity of ozone exposure is much less extensive. In male rats exposed to 1 ppm ozone for 20 months, epithelial reorganization achieved a higher degree of structure than was observed with shorter exposure durations. The bronchial-like cells extended up to five airway generations into the gas exchange region (Pinkerton *et al.*, 1993). Thus, while the inflammatory response subsides, the morphological alterations persist. Pulmonary toxicity results in decreased host defense mechanisms, alterations in pulmonary immune mechanisms, and generally increased sensitivity to infectious agents (Gardner, 1982; Burleson *et al.*, 1989; Li and Richters, 1991; Gilmour *et al.*, 1993).

Humans

The role of ozone in human disease remains poorly defined, in part because ozone occurs in photochemical smog with a variety of other pollutants, including many particulates (Lippmann, 1989). Clinical studies have shown effects on pulmonary function in young adults, especially with exercise (Gong, 1992). Koren *et al.* (1991) have shown alterations in markers associated with pulmonary inflammation in humans exposed to ambient levels of ozone.

Systemic Toxicity

Hematologic effects have been reported in laboratory animals and humans after inhalation exposure to ozone, suggesting that ozone or ozone reaction products can cross the blood-gas barrier (USEPA, 1986). Behavioral and cardiovascular effects have also been reported and are summarized in the most recent ozone criteria document (USEPA, 1986). These effects are much more variable and less severe than the pulmonary effects that can be easily reproduced in most laboratories.

Carcinogenicity

Experimental Animals

There have been limited studies on the potential carcinogenicity of ozone in experimental animals. Hassett *et al.* (1985) reported a slight increase in the incidence of pulmonary adenomas in A/J mice following exposure to 0.31 or 0.5 ppm ozone for 6 months. There were a limited number of mice and the results are based on lung masses observed grossly. In Swiss Webster mice exposed to 0.4 or 0.8 ppm ozone for 18 weeks, there was no increase in the incidence of lung neoplasms (Last *et al.*, 1987). In a 13-month study of Wistar rats exposed to 0.05 ppm ozone, Ichinose and Sagai (1992) reported no increase in the incidence of lung neoplasms. Witschi *et al.* (1993) have reported that ozone does not affect the incidence of lung neoplasms in hamsters.

Humans

While there has been a dramatic increase in the incidence of lung neoplasms in this century, the great majority has been linked to cigarette smoking (Speizer, 1986) and there is no conclusive evidence to link ozone exposure to lung cancer in humans (Witschi, 1988).

Promotion Studies

There was no increase in the incidence of pulmonary adenomas in A/J mice treated with urethane and then exposed to 0.31 and 0.5 ppm ozone (Hassett *et al.*, 1985). There were a limited number of mice in this 6-month study. In urethane-treated A/J mice, there was no increase in the incidence of neoplasms in mice exposed to 0.4 ppm ozone but in mice exposed to 0.8 ppm there was an increase in the percentage of mice with neoplasms, but a decrease in the number of neoplasms per mouse (Last *et al.*, 1987). Ichinose

and Sagai (1992) reported an increase in the incidence of lung neoplasms in Wistar rats exposed to 0.05 ppm ozone exposure following a single injection of *N*-bis(2-hydroxypropyl) nitrosamine.

GENETIC TOXICITY

The genotoxicity data for ozone have been reviewed in detail by Victorin (1992). Briefly, this potent oxidizing agent is genotoxic in a variety of *in vivo* and *in vitro* bacterial, plant, and animal test systems. Many of the published test results are negative, however. The extreme reactivity, gaseous nature, and toxicity of ozone presented confounding influences in many of these tests; ozone concentrations must be carefully regulated to allow detection of mutagenicity in the absence of extreme toxicity. Also, this gas is highly labile and during prolonged exposure periods (a few hours or more), the ozone concentrations may fluctuate or drop, producing ineffective exposures. Voltage employed in the ozone generating apparatus, oxygen flow rate, and exposure time all appear to be important parameters for determining mutagenicity of ozone, particularly in bacterial studies (Dillon *et al.*, 1992). *In vitro*, ozone induced gene mutations in *Escherichia coli* K12 (Hamelin and Chung, 1974) and *Salmonella typhimurium* TA102 (Dillon *et al.*, 1992), dominant lethal mutations in *Drosophila melanogaster* (Erdman and Hernandez, 1982), chromosomal aberrations in cultured human lymphocytes (Gooch *et al.*, 1976), and fibroblasts (Guerrero *et al.*, 1979) and sister chromatid exchanges in Chinese hamster V79 cells (Shiraishi and Bandow, 1985) and human lymphocytes (Hsueh and Xiang, 1984).

In laboratory animals, exposure to ozone resulted in increased frequencies of chromosomal aberrations in lymphocytes of male and female Chinese hamsters (Tice *et al.*, 1978) and pulmonary macrophages of female F344 rats (Rithidech *et al.*, 1990), but not in lymphocytes of male C3H mice or bone marrow cells of Chinese hamsters (Gooch *et al.*, 1976). Again, in all these experiments, small differences in ozone concentration, exposure duration, and air flow may have been sufficient to produce these conflicting results. Also, lymphocytes (rather than bone marrow cells) may be a more reliable cell type to analyze for mutagenic effects of ozone due to the extreme biological reactivity of ozone.

Few *in vivo* investigations have been performed in humans exposed to ozone. Merz *et al.* (1975) reported increased frequencies of chromatid-type aberrations in the lymphocytes of six humans exposed to 0.5 ppm ozone for 6 or 10 hours, but other similar investigations yielded negative results (McKenzie *et al.*, 1977; Sarto and Viola, 1980; McKenzie, 1982). Additionally, no increase in SCEs was reported in lymphocytes of humans exposed to ozone (McKenzie *et al.*, 1977; Guerrero *et al.*, 1979; McKenzie, 1982). Interpretation of these human studies is made difficult by incomplete data presentations, lack of statistical analyses, inadequate number of study participants, inappropriate control subjects, or lack of attention to confounding factors such as additional exposures to hazards in the workplace or smoking history. Therefore, the genetic effects of ozone exposure in humans have not yet been determined.

STUDY RATIONALE

Growing concern over the health effects of oxidant air pollutants has stimulated considerable research. Because available literature was considered insufficient, the state of California and the Health Effects Institute (HEI) (a nonprofit research institute funded jointly by the USEPA and combustion engine manufacturers) nominated ozone for evaluation in long-term animal studies.

The standard 2-year studies were designed to include the present USEPA standard (0.12 ppm), the maximum concentration believed compatible with long-term survival (1 ppm), and an intermediate concentration (0.5 ppm). At the time the study designs were being considered, diesel exhaust studies in rodents had demonstrated that a majority of the neoplasms occurred after 24 months of exposure. Therefore, a second study with a 30-month exposure of the two highest concentrations was included. It was also recognized that ozone, while not acting as a direct carcinogen, could have important consequences if it promotes the carcinogenic process or acts as a cocarcinogen. Therefore, a third study was included in which male rats were exposed to an intermediate ozone concentration (0.5 ppm) and two levels (0.1 and 1.0 mg/kg) of a known pulmonary carcinogen 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) administered three times per week for 20 weeks. This tobacco-specific nitrosamine was considered a relevant carcinogen for people exposed to ozone since much is known about the carcinogenesis of NNK.

It was recognized that carcinogenicity was only one of the important endpoints of concern to policy makers, but to date most of the toxicity studies used relatively short exposure periods. Therefore, additional rats were added to the exposure chambers of the NTP studies for individual investigator-initiated research. These studies on pulmonary function, structure, and biochemistry were managed and supported by the Health Effects Institute (HEI).

Twenty months was selected as the maximum exposure because naturally occurring degenerative and neoplastic processes would not cause significant confounding problems for the investigators. Since only 164 rats were available for the nine studies supported by HEI, there was significant sharing of animals and tissues between investigators which, while limiting, did provide comparable data from the same study animals.

MATERIALS AND METHODS

PROCUREMENT AND CHARACTERIZATION

Ozone

Ultra-high purity compressed oxygen for the generation of ozone was obtained in nine lots. Lots 12636-11 and 12821-24 were manufactured by A.L. Welding Compressed Gases (Kennewick, WA). Lot 12636-11 was used throughout the 4-week studies and for part of the 2-year studies, and lot 12821-24 was used for part of the lifetime studies. Lot 12636-58 was manufactured by Alphagaz Specialty Gases, Division of Liquid Air Corporation (Denver, CO), and it was used for part of the 2-year and lifetime studies. Lots 12733-38, 12733-81, 12733-115, 12733-121, and 12733-142 were manufactured by Scott Specialty Gases (Fremont, CA), and were used for part of the 2-year and lifetime studies. Lot 12821-7 was manufactured by Linde Gases (Torrance, CA), and it was used for part of the 2-year and lifetime studies.

A certification of oxygen purity was obtained from each of the vendors, which showed that the supplied compressed oxygen purity was greater than or equal to 99.9%. Oxygen purity was acceptable for the studies.

4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone

The 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) was obtained from Chemsyn Science Laboratories (Lenexa, KS) in one lot (86-034-01-06). Identity, purity, and stability analyses were conducted by Research Triangle Institute (RTI) (Research Triangle Park, NC). Reports on analyses performed in support of the NNK studies are on file at the National Institute of Environmental Health Sciences (NIEHS). The methods and results of these studies are detailed in Appendix L.

The chemical, a yellow crystalline solid, was identified as NNK by infrared, ultraviolet/visible, nuclear magnetic resonance, and mass spectroscopy. The purity was determined by Karl Fischer water analysis, thin-layer chromatography, and high-performance liquid chromatography. Karl Fischer water analysis indicated 0.57% ± 0.01% water. Thin-layer chromatography by two systems indicated one spot and no impurities. High-performance liquid chromatography using two systems revealed no impurities, and separated the two geometric isomers E (88%) and Z (12%). The overall purity was determined to be greater than 99%. Subsequent purity analyses performed by the study laboratory using gas chromatography methods also found the overall purity to be greater than 99%. Stability studies of the bulk chemical were performed by RTI, using high-performance liquid chromatography. NNK was determined to be stable as a bulk chemical for at least 2 weeks when stored in the dark at temperatures of up to 26° C. To ensure stability, the bulk chemical was stored in the original container under a nitrogen blanket protected from light at approximately 5° C.

Trioctanoin

Trioctanoin was obtained from Eastman Kodak Company (Rochester, NY) in one lot, which was assigned lot number MO61289. Midwest Research Institute (MRI), (Kansas City, MO) had identified the chemical, a light yellow transparent liquid, as trioctanoin by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy. All spectra were consistent with the structure of trioctanoin.

The purity was determined by Karl Fisher water analysis; elemental analysis; titrations for acid value, saponification value, and ester value; thin-layer chromatography; and gas chromatography. Karl Fischer water analysis indicated less than 0.1% water. Elemental analyses for carbon and hydrogen were in agreement with the theoretical values for trioctanoin. From the titration results, a purity of 93% of the theoretical value was determined. Thin-layer chromatography indicated a major band and a minor and three trace impurities. Analysis by gas chromatography indicated a major peak and several impurity peaks with a cumulative area of approximately 7%

relative to the major peak. The largest impurity (5.1%) was identified by gas chromatography as dioctanoin. No attempt was made to determine the relative amounts of the two isomers. The study laboratory analyzed the bulk chemical for peroxide content. All of the trioctanoin used for dose preparation was found to have a peroxide content of less than 3 mEq/kg. Stability studies of the bulk chemical were performed by MRI, using gas chromatography. Trioctanoin was determined to be stable as a bulk chemical for 2 weeks when stored protected from light at temperatures up to 60° C. To ensure stability, the bulk chemical was stored in containers with a nitrogen headspace at room temperature protected from light.

PREPARATION AND ANALYSIS OF DOSE FORMULATIONS

NNK/Trioctanoin

Dose formulations (NNK in trioctanoin) were prepared every 3 weeks by mixing NNK with trioctanoin (Table L1). Stability analysis of the 0.1 mg/g dose formulation was performed by high-performance liquid chromatography. Stability was confirmed for 3 weeks when stored at room temperature. Periodic analyses of the dose formulations were conducted at the study laboratory using high-performance liquid chromatography. Dose formulations were analyzed at the start, middle and end of the 20-week NNK exposure period. All dose formulations used for the study were within specifications except for the initial 0.1 mg/mL formulation (approximately 78% of the target), which was discarded and replaced by a sample within specifications. All animal room samples were within 10% of the target concentrations (Table L2).

GENERATION AND MONITORING OF CHAMBER CONCENTRATIONS

Ozone gas was generated from greater than 99.9% pure oxygen using a silent arc (corona) discharge ozonator (Model O3V5-O, OREC, Phoenix, AZ). The concentration in each chamber was controlled by manually adjusting the individual chamber metering valves. Detailed descriptions of the inhalation chambers are contained in Appendix L.

Chamber concentrations were monitored using an ultraviolet spectrophotometric analyzer (Dasibi Model 1003-AH or Dasibi Model 1003-PC systems) (Glendale, CA). For both monitoring systems, air sampled at each location was transported to the monitor by transfer lines of Teflon® tubing. Samples were directed to the ozone monitor through a set of eight computer-controlled, multiplexed Teflon valves. A sampling rate of 4 minutes per port assured that all ports were sampled approximately twice per hour. Each on-line monitor was calibrated by correlating the analog output of the on-line monitor with concentrations obtained using an independently calibrated, portable ozone monitor (Dasibi Model 1003-AH).

The buildup of vapor concentration in the chamber at the beginning of exposure to 90% of its final stable concentration (T_{90}) and the decay of concentration at the end of exposure to 10% (T_{10}) were measured prior to the start of each study in chambers with a full complement of mature F344/N rats and B6C3F$_1$ mice. These tests were done in conjunction with the prestart tests for the 4-week, 2-year, and lifetime ozone studies. The measurements were repeated once after the start of the 4-week, 2-year, and lifetime studies. At a chamber airflow rate of 15 air changes/hour, the theoretical values for T_{90} and T_{10} are both approximately 12.5 minutes. A T_{90} value of 30 minutes was used based on the experimental data. The T_{10} value ranged from 5 to 11 minutes.

Tests with ozone in a standard H-2000 chamber with animals present and a standard fresh air flow rate of 15 air changes per hour indicated that acceptable uniformity of the test article was not achievable. Concentration uniformity was improved by mixing the air within the chamber with enough energy through recycling that the rate of depletion of ozone was limited primarily by the ability of the animals or other surfaces to react with the chemical and not by diffusion of the chemical within the chamber. This was accomplished by using a recirculation device that increased the velocity of the air movement (Figure L6). Uniformity of ozone concentration in the exposure chambers was measured once during the 4-week studies and quarterly during the 2-year and lifetime studies. The usual criteria for between-port variance is less than or equal to 5%. While the majority of the determinations were within this range, some exceeded this value, and 10.1% was the maximum value found.

Summaries of the chamber concentrations in the 4-week and 2-year ozone studies, the ozone/NNK study, and the lifetime ozone studies are presented in Tables L3 through L6. The monthly mean exposure concentrations are presented in Figures L7 through L18.

4-WEEK OZONE STUDIES

The NTP study designs were a result of a series of meetings at the National Institute of Environmental Health Sciences (NIEHS) with scientists from NIEHS, the United States Environmental Protection Agency (USEPA), and the Health Effects Institute (HEI), as well as experts from academic institutions working in the area of air pollutants.

The 4-week ozone studies were conducted to characterize ozone toxicity, identify target organs, establish the differences between the sexes in sensitivity to ozone exposure, and to determine the appropriate concentrations to be used in the 2-year and lifetime studies.

Male and female F344/N rats and B6C3F$_1$ mice were obtained from Simonsen Laboratories (Gilroy, CA). On receipt, the rats and mice were approximately 4 weeks old. Animals were quarantined for 13 days before exposure began. Before the beginning of the studies, two male and two female rats and mice were randomly selected for health evaluations. Three weeks after receipt, serologic analyses were performed on five male and five female rats and mice; these animals were not a part of the 4-week ozone study and were maintained in control chambers. Sentinel animal analyses were performed according to the protocols of the NTP Sentinel Animal Program (Appendix N).

Groups of five male and five female rats and mice were exposed to ozone at concentrations of 0, 0.5, or 1.0 ppm. Animals were in the chambers for 12 minutes before T_{90} was reached; thus, animals were exposed 6 hours and 12 minutes per day (excluding weekends) for 20 exposure days during a 4-week period. Feed and water were available *ad libitum*, except during exposure periods. Rats and mice were housed individually following the quarantine period. Clinical findings were recorded daily for rats and mice. The animals were weighed initially, weekly, and at the end of the studies. Details of the study design and animal maintenance are summarized in Table 1.

A necropsy was performed on all animals. The heart, right kidney, liver, lung, right testis, and thymus were weighed. Tissues for microscopic evaluation were fixed and preserved in 10% neutral buffered formalin, processed and trimmed, imbedded in paraffin, sectioned to a thickness of 6 μm, and stained with hematoxylin and eosin. Complete histopathologic examinations were performed on all control and 1.0 ppm rats and mice. If a lesion was observed in the nose, larynx, lung, mediastinal or bronchial lymph nodes, or thymus, that organ was examined at the 0.5 ppm level also. Table 1 lists the tissues and organs examined.

2-YEAR AND LIFETIME OZONE STUDIES

Study Design

For the 2-year studies, groups of 50 male and 50 female rats and mice were exposed to ozone at concentrations of 0, 0.12, 0.5, or 1.0 ppm. Rats and mice were exposed for 6 hours per day, 5 days per week; at the beginning of each exposure period, rats and mice were in the chambers for approximately 30 minutes more to allow chamber exposure concentrations to reach T_{90}. Rats and mice were exposed in this manner for 105 weeks. In lifetime studies, groups of 50 male and 50 female rats and mice were exposed to ozone concentrations of 0, 0.5, or 1.0 ppm for 125 weeks (rats) or 130 weeks (mice).

Source and Specification of Animals

Male and female F344/N rats and B6C3F$_1$ mice were obtained from Simonsen Laboratories (Gilroy, CA) for use in the 2-year and lifetime ozone studies. Rats were quarantined for 14 days and mice for 21 days before the beginning of the studies. Five male and five female rats and three male and two female mice were selected for bacterial culture and selected histopathology prior to the beginning of the studies. Approximately 3 weeks after receipt, serology samples were collected for viral screening from up to seven male and seven female rats and two male and three female mice. Rats and mice were approximately 6 weeks old at the beginning of the studies. The health of the animals was monitored during the studies according to the protocols of the NTP Sentinel Animal Program (Appendix N).

Animal Maintenance

All animals were housed individually. Water was available *ad libitum*, and feed was available *ad libitum* except during exposure periods. Cage units were rotated vertically (2-year studies) or horizontally (lifetime studies) within each chamber weekly. Further details of animal maintenance are given in Table 1. Information on feed composition and contaminants is found in Appendix M.

Clinical Examinations and Pathology

All animals were observed twice daily for moribundity and mortality. Body weights were recorded initially, weekly for the first 13 weeks, monthly through week 92 (2-year studies) or week 91 (lifetime studies), then every 2 weeks until the end of the study. Clinical observations were made at 4-week intervals until the final 13 weeks of exposure, when they were recorded every 2 weeks.

A complete necropsy and microscopic examination were performed on all animals. At necropsy, all organs and tissues were examined for grossly visible lesions, and all major tissues were fixed and preserved in 10% neutral buffered formalin, processed and trimmed, embedded in paraffin, sectioned to a thickness of 5 to 6 μm, and stained with hematoxylin and eosin for microscopic examination. Tissues examined microscopically are listed in Table 1.

2-YEAR OZONE/NNK STUDY

Study Design

Groups of 48 male rats were exposed to ozone at concentrations of 0 or 0.5 ppm, 6 hours per day, 5 days per week (exclusive of holidays) for 105 weeks. The same groups of 48 rats were injected subcutaneously with trioctanoin alone or with 0.1 or 1.0 mg 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) in trioctanoin per kg body weight three times weekly for the first 20 weeks of the study. At the beginning of each exposure period, rats were in the chambers for approximately 30 minutes to allow chamber exposure concentrations to reach T_{90}.

Source and Specification of Animals

Male F344/N rats were obtained from Simonsen Laboratories (Gilroy, CA) for use in the 2-year ozone/NNK study. Rats were quarantined for 12 days before the beginning of the studies. Ten male rats were selected for bacterial culture and selected histopathology prior to the beginning of the study. Twenty-one days after receipt, serology samples were collected from 10 rats for viral screening. Rats were approximately 6 weeks old at the beginning of the studies. The health of the animals was monitored during the studies according to the protocols of the NTP Sentinel Animal Program (Appendix N).

Animal Maintenance

Rats were housed individually. Water was available *ad libitum*, and feed was available *ad libitum* except during exposure periods. Cage units were rotated vertically within each chamber weekly. Further details of animal maintenance are given in Table 1. Information on feed composition and contaminants is provided in Appendix M.

Clinical Examinations and Pathology

All animals were observed twice daily for morbidity and mortality. Clinical findings and body weights were recorded at the beginning of the study, weekly for 20 weeks, then monthly through week 92, then every 2 weeks until the end of the study.

A complete necropsy and microscopic examination were performed on all animals. At necropsy, all organs and tissues were examined for grossly visible lesions, and all major tissues were fixed and preserved in 10% neutral buffered formalin, processed and trimmed, embedded in paraffin, sectioned to a thickness of 5 to 6 μm, and stained with hematoxylin and eosin for microscopic examination. Tissues examined microscopically are listed in Table 1.

Microscopic evaluations were completed by the study laboratory pathologist, and the pathology data were entered into the Toxicology Data Management System. The microscopic slides, paraffin blocks, and residual wet tissues were sent to the NTP Archives for inventory, slide/block match, and wet tissue audit. The slides, individual animal data records, and pathology tables were evaluated by an independent quality assessment laboratory. The individual animal records and tables were compared for accuracy, the slide and tissue counts were verified, and the histotechnique was evaluated. For the ozone studies, a quality assessment pathologist reviewed the lung, nose, and larynx from all animals. In addition, the thyroid was reviewed in male rats, and the clitoral gland was reviewed in female rats.

The quality assessment report and slides were submitted to the NTP Pathology Working Group (PWG) chair, who reviewed the selected tissues and any other tissues for which a disagreement in diagnosis between the laboratory and quality assessment pathologists existed. Representative histopathology slides containing examples of lesions related to chemical administration, examples of disagreements in diagnoses between the laboratory and quality assessment pathologist, or lesions of general interest were presented by the chair to the PWG for review. The PWG consisted of the quality assessment pathologist and other pathologists experienced in rodent toxicologic pathology. This group examined the tissues without any knowledge of dose groups or previously rendered diagnoses. When the PWG consensus differed from the opinion of the laboratory pathologist, the diagnosis was changed. Thus, the final diagnoses represent a consensus of contractor pathologists and the PWG. Details of these review procedures have been described, in part, by Maronpot and Boorman (1982) and Boorman *et al.* (1985). For subsequent analyses of the pathology data, the diagnosed lesions for each tissue type were evaluated separately or combined according to the guidelines of McConnell *et al.* (1986).

Statistical Methods

Survival Analyses

The probability of survival was estimated by the product-limit procedure of Kaplan and Meier (1958) and is presented in the form of graphs. Animals found dead of other than natural causes were censored from the survival analyses; animals dying from natural causes were not censored. Statistical analyses for possible dose-related effects on survival used Cox's (1972) method for testing two groups for equality and Tarone's (1975) life table test to identify dose-related trends. All reported P values for the survival analyses are two sided.

Calculation of Incidence

The incidences of neoplasms or nonneoplastic lesions as presented in Tables A1, A5, B1, B5, C1, C5, D1, D5, E1, E4, F1, F4, G1, G4, H1, H4, I1, and I4 are given as the number of animals bearing such lesions at a specific anatomic site and the number of animals with that site examined microscopically. For calculation of statistical significance, the incidences of most neoplasms (Tables A3, B3, C3, D3, E3, F3, G3, H3, and I3) and all nonneoplastic lesions are given as the numbers of animals affected at each site examined microscopically. However, when macroscopic examination was required to detect neoplasms in certain tissues (e.g., skin, intestine, harderian gland, and mammary gland) before microscopic evaluation, or when neoplasms had multiple potential sites of occurrence (e.g., leukemia or lymphoma), the denominators consist of the number of animals on which a necropsy was performed.

Analysis of Neoplasm Incidences

The majority of neoplasms in these studies were considered to be incidental to the cause of death or not rapidly lethal. Thus, the primary statistical method used was logistic regression analysis, which assumed that the diagnosed neoplasms were discovered as the result of death from an unrelated cause and thus did not affect the risk of death. In this approach, neoplasm prevalence was modeled as a logistic function of chemical exposure and time. Both linear and quadratic terms in time were incorporated initially, and the quadratic term was eliminated if the fit of the model was not significantly enhanced. The neoplasm incidences of exposed and control groups were compared on the basis of the likelihood score test for the regression coefficient of dose. This method of adjusting for intercurrent mortality is the prevalence analysis of Dinse and Lagakos (1983), further described and illustrated by Dinse and Haseman (1986). When neoplasms are incidental, this comparison of the time-specific neoplasm prevalences also provides a comparison of the time-specific neoplasm incidences (McKnight and Crowley, 1984).

In addition to logistic regression, other methods of statistical analysis were used, and the results of these tests are summarized in the appendixes. These methods include the life table test (Cox, 1972; Tarone, 1975), appropriate for rapidly lethal neoplasms, and the Fisher exact test and the Cochran-Armitage trend test (Armitage, 1971; Gart *et al.*, 1979), procedures based on the overall proportion of neoplasm-bearing animals.

Tests of significance included pairwise comparisons of each exposed group with controls and a test for an overall dose-related trend. Continuity-corrected tests were used in the analysis of neoplasm incidence, and reported P values are one sided. The procedures described in the preceding paragraphs were also used to evaluate selected nonneoplastic lesions. For further discussion of these statistical methods, refer to Haseman (1984).

Analysis of Nonneoplastic Lesion Incidences

Because all nonneoplastic lesions in this study were considered to be incidental to the cause of death or not rapidly lethal, the primary statistical analysis used was a logistic regression analysis in which nonneoplastic lesion prevalence was modeled as a logistic function of chemical exposure and time. For lesions detected at the interim evaluation, the Fisher exact test was used, a procedure based on the overall proportion of affected animals.

Analysis of Continuous Variables

Organ and body weight data, which have approximately normal distributions, were analyzed using the parametric multiple comparison procedures of Dunnett (1955) and Williams (1971, 1972). Jonckheere's test (Jonckheere, 1954) was used to assess the significance of the dose-related trends and to determine whether a trend-sensitive test (Williams' test) was more appropriate for pairwise comparisons than a test that does not assume a monotonic dose-related trend (Dunnett's test). Average severity values were analyzed for significance using the Mann-Whitney U test (Hollander and Wolfe, 1973).

Historical Control Data

Although the concurrent control group is always the first and most appropriate control group used for evaluation, historical control data can be helpful in the overall assessment of neoplasm incidence in certain instances. Consequently, neoplasm incidences from the NTP historical control database (Haseman *et al.*, 1984, 1985) are included in the NTP reports for neoplasms appearing to show compound-related effects.

Quality Assurance Methods

The 2-year and lifetime studies were conducted in compliance with Food and Drug Administration Good Laboratory Practice Regulations (21 CFR, Part 58). In addition, as records from the 2-year and lifetime studies were submitted to the NTP Archives, these studies were audited retrospectively by an independent quality assurance contractor. Separate audits covering completeness and accuracy of the pathology data, pathology specimens, final pathology tables, and board draft of this NTP Technical Report were conducted. Audit procedures and findings are presented in the reports and are on file at NIEHS. The audit findings were reviewed and assessed by NTP staff, so all comments had been resolved or were otherwise addressed during the preparation of this Technical Report.

GENETIC TOXICOLOGY

The genetic toxicity of ozone was assessed by testing the ability of the chemical to induce mutations in various strains of *Salmonella typhimurium*. The protocol for these studies and the results are given in Appendix J.

The genetic toxicity studies of ozone are part of a larger effort by the NTP to develop a database that would permit the evaluation of carcinogenicity in experimental animals from the structure and responses of the chemical in short-term *in vitro* and *in vivo* genetic toxicity tests. These genetic toxicity tests were originally developed to study mechanisms of chemically induced DNA damage and to predict carcinogenicity in animals, based on the electrophilic theory of chemical carcinogenesis and the somatic mutation theory (Miller and Miller, 1977; Straus, 1981; Crawford, 1985).

There is a strong correlation between a chemical's potential electrophilicity (structural alert to DNA reactivity), mutagenicity in *Salmonella*, and carcinogenicity in rodents. The combination of electrophilicity and *Salmonella* mutagenicity is highly correlated with the induction of carcinogenicity in rats and mice and/or at multiple tissue sites (Ashby and Tennant, 1991). Other *in vitro* genetic toxicity tests do not correlate well with rodent carcinogenicity (Tennant *et al.*, 1987; Zeiger *et al.*, 1990), although these other tests can provide information on the types of DNA and chromosome effects that can be induced by the chemical being investigated. Data from NTP studies show that a positive response in *Salmonella* is currently the most predictive *in vitro* test for rodent carcinogenicity (89% of the *Salmonella* mutagens were rodent carcinogens), and that there is no complementarity among the *in vitro* genetic toxicity tests. That is, no battery of tests that included the *Salmonella* test improved the predictivity of the *Salmonella* test alone. The predictivity for carcinogenicity of a positive response in bone marrow chromosome aberration or micronucleus tests is not yet defined.

4-Week Studies	2-Year Ozone Studies	Lifetime Ozone Studies	2-Year Ozone/NNK Study
Histopathology Complete histopathology was performed on 0 and 1.0 ppm rats and mice. In addition to gross lesions and tissue masses, the tissues examined included: adrenal gland, brain, clitoral gland (rats), esophagus, femur, gallbladder (mice), heart, large intestine (cecum, colon, rectum), small intestine (duodenum, jejunum, ileum), kidney, liver, lungs, lymph nodes (bronchial and mediastinal), mammary gland (with adjacent skin), muscle (thigh), nose, ovaries, pancreas, parathyroid gland, pituitary gland, preputial gland (rats), prostate gland, salivary gland, spleen, stomach, testes (with epididymis and seminal vesicle), thymus, thyroid gland, trachea, urinary bladder, and uterus. In addition, larynx, bronchial and mediastinal lymph nodes, lungs, nose (three sections), thymus, and trachea were examined in 0.5 ppm groups if lesions present in 1.0 ppm group.	Complete histopathology was performed on all rats and mice. In addition to gross lesions and tissue masses, the tissues examined included: adrenal gland, brain, clitoral gland (rats), esophagus, femur, gallbladder (mice), heart, large intestine (cecum, colon, rectum), small intestine (duodenum, jejunum, ileum), kidney, larynx, liver, lungs, lymph nodes (mandibular, mesenteric, bronchial, and mediastinal), mammary gland (with adjacent skin), nose, ovaries, pancreas, parathyroid gland, pituitary gland, preputial gland (rats), prostate gland, salivary gland, spleen, stomach, testes (with epididymis and seminal vesicle), thymus, thyroid gland, trachea, urinary bladder, and uterus.	Complete histopathology was performed on all rats and mice. In addition to gross lesions and tissue masses, the tissues examined included: adrenal gland, brain, clitoral gland (rats), esophagus, femur, gallbladder (mice), heart, large intestine (cecum, colon, rectum), small intestine (duodenum, jejunum, ileum), kidney, larynx, liver, lungs, lymph nodes (mandibular, mesenteric, bronchial, and mediastinal), mammary gland (with adjacent skin), nose, ovaries, pancreas, parathyroid gland, pituitary gland, preputial gland (rats), prostate gland, salivary gland, spleen, stomach, testes (with epididymis and seminal vesicle), thymus, thyroid gland, trachea, urinary bladder, and uterus.	Histopathology was performed on all animals. In addition to gross lesions and tissue masses, the tissues examined included: lymph nodes (bronchial and mediastinal), lungs, nose, larynx, and trachea.

RESULTS

RATS

4-WEEK STUDY

All rats survived to the end of the study (Table 2). The final mean body weights and mean body weight gains of 0.5 ppm males and females and of 1.0 ppm females were similar to those of the controls. The final mean body weight of 1.0 ppm males was 7% lower than that of the controls.

Clinical findings during the study included hypoactivity and decreased urine and fecal output in 1.0 ppm males and females and ruffled fur in exposed groups of males.

Absolute and relative lung weights of all exposed groups of males and females were greater than those of the controls, and the increases were considered to be related to ozone exposure (Table K1). The absolute lung weight of 1.0 ppm females was significantly greater than that of the controls, as were the relative lung weights of 1.0 ppm males and females. Absolute and relative thymus weights of all exposed groups generally decreased with increasing exposure level, and the absolute and relative thymus weights of 1.0 ppm females were significantly less than those of the controls.

Male and female rats exposed to 0.5 or 1.0 ppm ozone developed patchy, multifocal lesions of the lung involving the centriacinar region; the lesions consisted of infiltration of granulocytes and macrophages with extension of the bronchial epithelium into the alveolar ducts. In addition, exposed groups of males and females developed hyperplasia of the cuboidal nonciliated (transitional) epithelium along the lateral wall of the nasal passage. Female rats exposed to ozone developed minimal squamous metaplasia of the laryngeal epithelium at the base of the epiglottis.

2-YEAR OZONE STUDY

Survival

Estimates of survival probabilities for male and female rats exposed to ozone by inhalation for 2 years are presented in Table 3 and in Kaplan-Meier survival curves (Figure 1). Two-year survival rates of exposed rats were similar to those of the controls.

Body Weights and Clinical Findings

The mean body weights of 0.12 and 0.5 ppm males and females were similar to those of the controls throughout the study, as were the final mean body weights of rats in these exposure groups (Tables 4 and 5 and Figure 2). The mean body weights of 1.0 ppm males and females were slightly lower than those of the controls throughout the study. The final mean body weights of 1.0 ppm males and females were approximately 6% lower than those of the controls.

Hypoactivity was observed in male and female rats exposed to ozone. Rats, particularly those exposed to 1.0 ppm, were less active during and immediately after exposure.

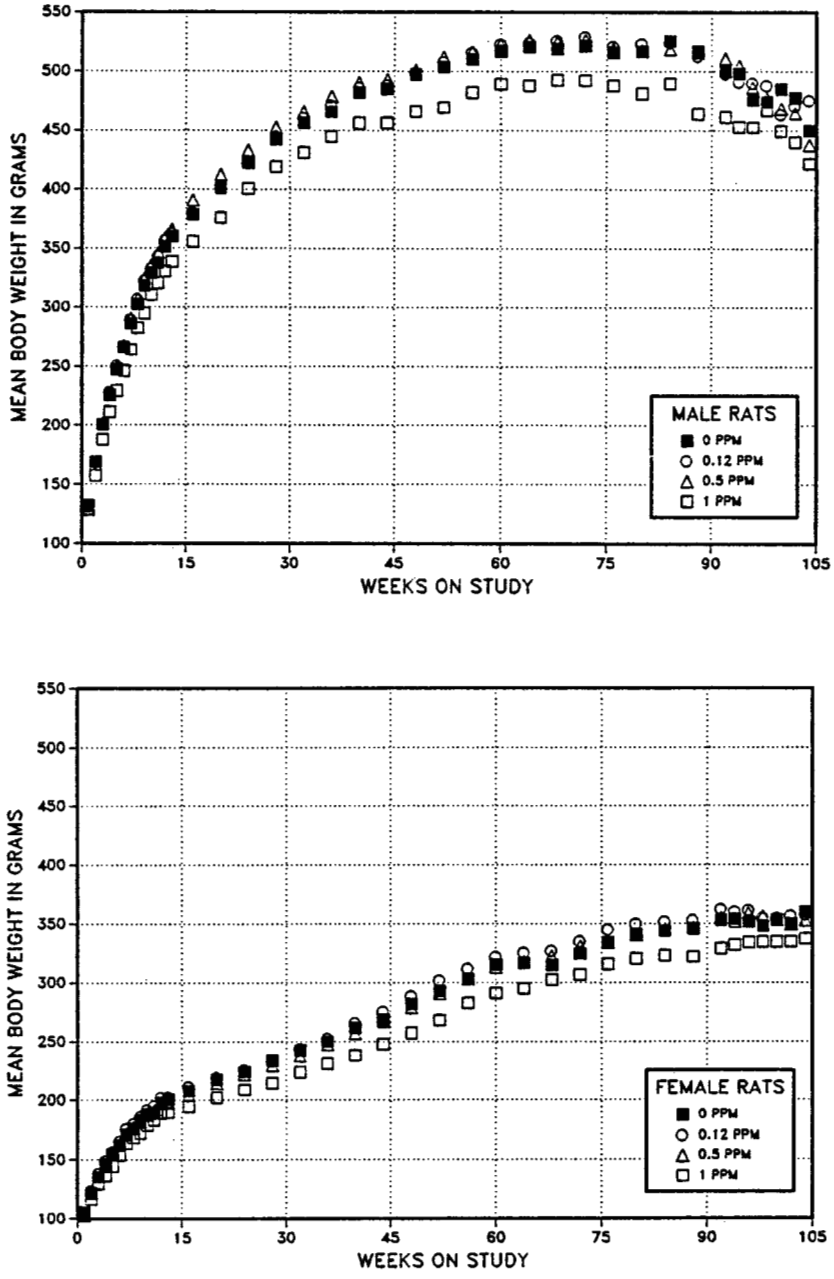

FIGURE 2
Growth Curves for Male and Female Rats Exposed to Ozone by Inhalation for 2 Years

Pathology and Statistical Evaluation

This section describes the statistically significant or biologically noteworthy changes in the incidences of nonneoplastic lesions in the lung, nose, and larynx. Summaries of the incidences of neoplasms and nonneoplastic lesions, individual animal respiratory system tumor diagnoses, and statistical analyses of primary neoplasms that occurred with an incidence of at least 5% in at least one animal group are presented in Appendix A for male rats and Appendix B for female rats.

Lung: Males and females exposed to ozone developed increased incidences of metaplasia, inflammation (histiocytic infiltration), and fibrosis (Table 6). The most prominent ozone-related pulmonary lesion was the patchy, multifocal centriacinar extension of cuboidal (ciliated and nonciliated) epithelium into the proximal avleoli and along the alveolar septa. Some of the cuboidal cells appeared to have apical blebs consistent with Clara cells. Because these were uncommon lesions of mild severity in 0.12 ppm rats and were present in nearly all animals exposed to 0.5 or 1.0 ppm, they were clearly ozone concentration dependent. There was an increase in the number of macrophages in the centriacinar alveoli and there was increased thickness (fibrosis) of the adjacent alveolar septa. There was no ozone-related increased incidence of pulmonary neoplasms.

Nose: There were increased incidences of inflammation, hyperplasia, and metaplasia in the nasal passages of rats exposed to ozone (Table 6). Goblet cell hyperplasia was characterized by an increased number of goblet cells within the respiratory epithelium, and hyperplasia of the transitional epithelium was characterized by increased thickness of the cuboidal cell layer. Exposed groups of rats developed flattened and patchy squamous metaplasia of the anterior portion of the transitional epithelium along the lateral wall and on the tips of the maxilloturbinates and nasoturbinates. Increased numbers of lymphocytes and macrophages occurred in the nasal mucosa and increased numbers of granulocytes were observed in the nasal passage. Suppurative inflammation appeared to be more prominent in males than in females.

Larynx: Incidences of metaplasia were observed in the larynx of exposed rats (Table 6), and the lesion was characterized by one or more layers of flattened cells in areas where the epithelium is typically more cuboidal. Ciliated cells which can be occasionally observed were, for the most part, absent in rats exposed to 0.5 or 1.0 ppm ozone.

* Significantly different (P≤0.05) from the control group by the logistic regression test
** P≤0.01
[a] Number of animals with organ examined microscopically
[b] Number of animals with lesion
[c] Average severity grade of lesions in affected animals (1=minimal; 2=mild; 3=moderate; 4=marked).
[d] Number of animals with neoplasm per number of animals necropsied
[e] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[f] Observed incidence at terminal sacrifice
[g] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The logistic regression test regards these lesions as nonfatal.
[h] Historical incidence for 2-year inhalation studies with untreated control groups (mean ± standard deviation): 17/398 (4.3% ± 4.5%); range, 0%-10%
[i] Historical incidence: 4/398 (1.0% ± 1.5%); range, 0%-4%
[j] Not applicable; no neoplasms in animal group

LIFETIME STUDY

Survival

Estimates of survival probabilities for male and female rats exposed to ozone by inhalation for 125 weeks are presented in Table 7 and in Kaplan-Meier survival curves (Figure 3). Survival rates of exposed rats were similar to those of the controls.

Body Weights and Clinical Findings

The mean body weights and body weight gains of 1.0 ppm males and females were slightly lower than those of the controls throughout most of the study (Tables 8 and 9 and Figure 4). However, the final mean body weight of all exposed groups were similar to those of the controls.

Hypoactivity was observed in male and female rats exposed to ozone. Rats, particularly those exposed to 1.0 ppm, were less active during and immediately after exposure.

TABLE 7
Survival of Rats in the Lifetime Inhalation Study of Ozone

	0 ppm	0.5 ppm	1.0 ppm
Male

Growth Curves for Male and Female Rats Exposed to Ozone by Inhalation for 124 Weeks

Pathology and Statistical Evaluation

This section describes the statistically significant or biologically noteworthy changes in the incidences of nonneoplastic lesions in the lung, nose, and larynx. Summaries of the incidences of neoplasms and nonneoplastic lesions, individual animal respiratory system tumor diagnoses, and statistical analyses of primary neoplasms that occurred with an incidence of at least 5% in at least one animal group, are presented in Appendix F for male rats and Appendix G for female rats.

Lung: Increased incidences of metaplasia, inflammation (histiocytic infiltration), and fibrosis occurred in males and females exposed to 0.5 or 1.0 ppm ozone (Table 10). The ozone-related multifocal centriacinar extension of cuboidal (ciliated and nonciliated) epithelium into the proximal alveoli and along the alveolar septa was similar to that observed in the 2-year study. There was an increase in the number of macrophages in the centriacinar alveoli and increased thickness (fibrosis) of the adjacent alveolar septa. The interstitial fibrosis was more prominent than that observed in the 2-year study. No increased incidences of lung neoplasms were observed.

Nose: Increased incidences of hyperplasia and squamous cell metaplasia were observed in the nasal passages of males and females exposed to 0.5 or 1.0 ppm ozone (Table 10). As in the 2-year study, both goblet cell hyperplasia and hyperplasia of the transitional epithelium were observed. Increased incidences of inflammation were not observed (Tables F4 and G4).

Larynx: Increased incidences of squamous metaplasia occurred in the epiglottis of 0.5 and 1.0 ppm males and females (Table 10). The metaplasia was characterized by one or more layers of flattened cells in areas where the epithelium is typically low cuboidal and appeared similar to that observed in the 2-year studies.

Logistic regression test	P=0.594N	P=0.598	P=0.738N

** Significantly different (P≤0.01) than the control group by the logistic regression test
[a] Number of animals with organ examined microscopically
[b] Number of animals with lesion
[c] Average severity grade of lesions in affected animals (1=minimal; 2=mild; 3=moderate; 4=marked).
[d] Number of animals with neoplasm per number of animals necropsied
[e] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[f] Observed incidence at terminal sacrifice
[g] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The logistic regression test regards these lesions as nonfatal. A negative trend or a lower incidence in an exposure group is indicated by N.
[h] Not applicable; no neoplasms in animal group

2-YEAR OZONE/NNK STUDY

Survival

Estimates of survival probabilities for male rats exposed to ozone and 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK) or NNK only are presented in Table 11 and in Kaplan-Meier survival curves (Figure 5). Two-year survival rates of all groups of exposed male rats were similar.

Body Weights and Clinical Findings

Final mean body weights of all males exposed to NNK alone or NNK and ozone were similar to that of the controls, with the exception of rats exposed to 1.0 mg NNK/kg body weight and 0.5 ppm ozone. The mean body weights of exposed and control groups were similar throughout the study (Table 12 and Figure 6).

Hypoactivity was observed in males exposed to NNK and ozone and in those exposed to NNK without ozone. Rats were less active during and immediately after exposure.

TABLE 11
Survival of Male Rats in the 2-Year Inhalation Study of Ozone/NNK

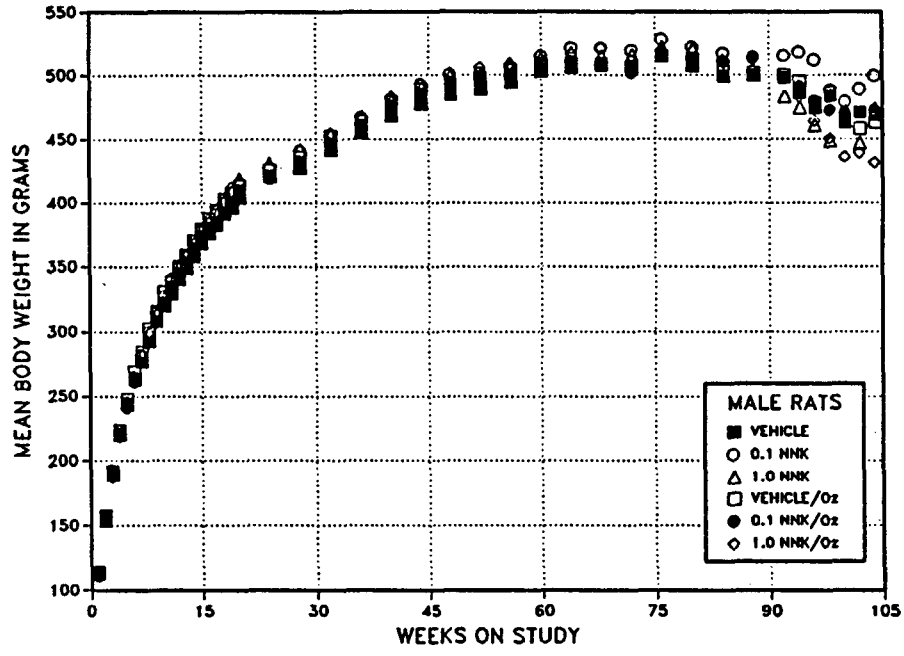

FIGURE 6
Growth Curves for Male Rats Exposed to Ozone or Ozone/NNK by Inhalation for 2 Years

Pathology and Statistical Evaluation

This section describes the statistically significant or biologically noteworthy changes in the incidences of nonneoplastic lesions in the lung and nose. Summaries of the incidences of nonneoplastic lesions, individual animal respiratory system tumor diagnoses, and statistical analyses of primary neoplasms that occurred with an incidence of at least 5% in at least one animal group are presented in Appendix E.

Lung: Alveolar epithelial metaplasia and interstitial fibrosis occurred in all groups of rats exposed to ozone (with or without NNK), but were not observed in vehicle controls or in animals exposed to NNK alone (Table 13). The incidence of alveolar cellular infiltration was greater in males exposed to ozone than in the vehicle control males. There was a dose-related increased incidence of atypical alveolar hyperplasia in groups of rats receiving NNK, and the increase was significant. An increased incidence of alveolar/bronchiolar adenoma or carcinoma (combined) also occurred in rats administered 1.0 mg/kg NNK, with or without ozone. The administration of ozone did not affect the occurrence of pulmonary neoplasms or nonneoplastic lesions in rats administered NNK.

Nose: The incidence of hyperplasia in groups of rats exposed to ozone with and without NNK was greater than the incidence in males not exposed to ozone. Incidences of hyperplasia among groups of rats exposed only to NNK were low and similar to that of the controls (Table 13). The nasal lesions were similar to those seen in rats exposed to ozone by inhalation for 2 years.

TABLE 13
Incidences of Selected Neoplasms and Nonneoplastic Lesions in Male Rats in the 2-Year Inhalation Study of Ozone/NNK

(Dose)	Vehicle Control	Vehicle Control/ 0.5 ppm Ozone	0.1 mg/kg NNK/ 0 ppm Ozone	0.1 mg/kg NNK/ 0.5 ppm Ozone	1.0 mg/kg NNK/ 0 ppm Ozone	1.0 mg/kg NNK/ 0.5 ppm Ozone

Overall rate[d]	3/48 (6%)	1/48 (2%)	2/48 (4%)	3/48 (6%)	23/48 (48%)	28/48 (58%)
Adjusted rate[e]	37.5%	3.2%	7.7%	35.1%	93.2%	100.0%
Terminal rate[f]	3/8 (38%)	0/3 (0%)	0/6 (0%)	2/6 (33%)	3/4 (75%)	5/5 (100%)
First incidence (days)	736 (T)	590	625	565	429	557
Logistic regression[g]		P=0.442N	P=0.591N	P=0.627	P<0.001	P<0.001

* Significantly different (P≤0.05) than the control group by the logistic regression test
** P≤0.01
(T) Terminal sacrifice
a Number of animals with organ examined microscopically
b Number of animals with lesion
c Average severity grade of lesions in all animals (1=minimal; 2=mild; 3=moderate; 4=marked).
d Number of animals with neoplasm per number of animals necropsied
e Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
f Observed incidence at terminal sacrifice
g Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the vehicle controls and that exposed group. The logistic regression test regards these lesions as nonfatal. A lower incidence in an exposure group is indicated by N.

MICE

4-WEEK STUDY

All mice survived to the end of the study (Table 14). The final mean body weights and body weight gains of all exposed groups of mice were less than those of the controls. Hypoactivity was observed in 1.0 ppm mice throughout the study.

The relative lung weight of 1.0 ppm males was significantly greater than that of the controls (Table K2). There were no other statistically significant differences in absolute or relative organ weights in males or females.

Male and female mice exposed to 0.5 or 1.0 ppm ozone developed patchy, multifocal lesions of the lung involving the centriacinar region; the lesions consisted of infiltration of granulocytes and macrophages with extension of the bronchial epithelium into the alveolar ducts. Slight hyperplasia of ciliated and nonciliated cells was observed in the cuboidal epithelium of the alveolar ducts with a minimal histiocytic infiltrate. In addition, exposed groups of males and females developed hyperplasia of the cuboidal nonciliated (transitional) epithelium along the lateral wall of the nasal passage with an increased number of neutrophils in the epithelial mucosa. No nonneoplastic lesions were observed in the larynx of mice.

TABLE 14
Survival and Body Weights of Mice in the 4-Week Inhalation Study of Ozone

Dose (ppm)	Survival[a]	Mean Body Weight[b] (g)			Final Weight Relative to Controls (%)
		Initial	Final	Change	
Male

[a] Number of animals surviving/number of animals initially in group
[b] Weights and weight changes are given as mean ± standard error.

2-YEAR STUDY

Survival

Estimates of survival probabilities for male and female mice exposed to ozone by inhalation for 2 years are presented in Table 15 and in Kaplan-Meier survival curves (Figure 7). Two-year survival rates of exposed groups of males and 0.12 and 0.5 ppm females were similar to that of the controls; 2-year survival rates of 1.0 ppm females were marginally greater than that of the controls.

Body Weights and Clinical Findings

The mean body weights of 0.12 and 0.5 ppm males were similar to those of the controls (Tables 16 and 17 and Figure 8). Mean body weights of 1.0 ppm males and of all exposed groups of females were less than those of the controls.

Hypoactivity was observed in male and female mice exposed to ozone. Mice, particularly those exposed to 1.0 ppm, were less active during and immediately after exposure.

TABLE 15

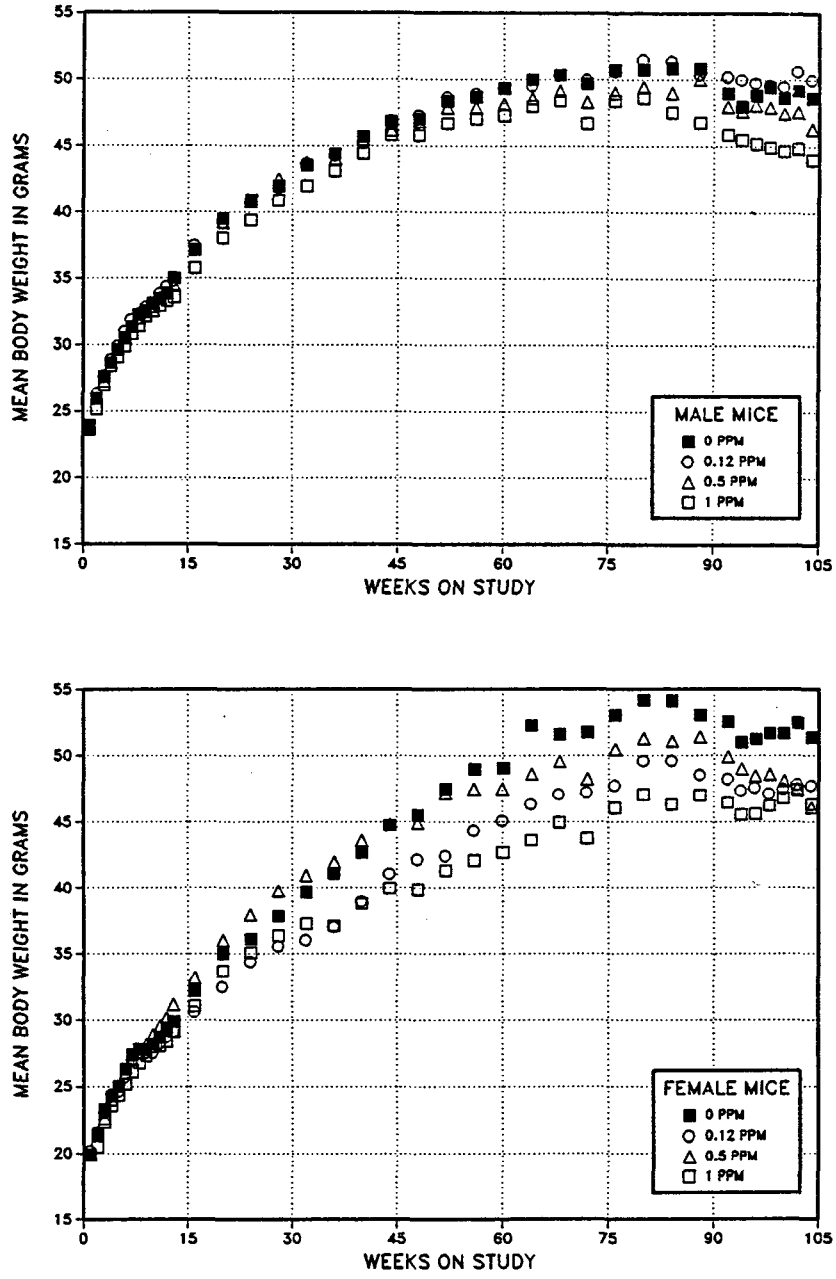

FIGURE 8
Growth Curves for Male and Female Mice Exposed to Ozone by Inhalation for 2 Years

Pathology and Statistical Evaluation

This section describes the statistically significant or biologically noteworthy changes in the incidences of neoplasms and nonneoplastic lesions in the lung, nose, larynx, and liver. Summaries of the incidences of neoplasms and nonneoplastic lesions, individual animal respiratory system tumor diagnoses, statistical analyses of primary neoplasms that occurred with an incidence of at least 5% in at least one animal group, and historical incidence data are presented in Appendix C for male mice and Appendix D for female mice.

Lung: The incidence of alveolar/bronchiolar neoplasms increased with increasing ozone exposure. The most prominent increased incidence was that of carcinomas in females. There was also an increase in the number of male mice with multiple adenomas (0 ppm, 0/50; 0.12 ppm, 0/50; 0.5 ppm, 3/50; 1.0 ppm, 1/50; Table C1). The incidence of multiple carcinomas in exposed males was similar to that in controls (2/50, 2/50, 4/50, 2/50; Table C1). One multiple adenoma occurred in a 1.0 ppm female (Table D1). The incidence of alveolar/bronchiolar adenoma or carcinoma (combined) occurred with a significant positive trend, and the incidence in 1.0 ppm females was significantly increased (Table 18). In addition, the incidence of alveolar/bronchiolar adenoma or carcinoma (combined) in 0.5 and 1.0 ppm females exceeded the NTP historical control range for this neoplasm (58/659; range, 0%-15%; Table D4).

Slight increased incidences of metaplasia occurred in the cuboidal (ciliated and nonciliated) epithelium in the alveolar ducts, with a minimal histiocytic infiltrate. These lesions were observed in 0.5 and 1.0 ppm males and females. There were no increased incidences of hyperplasia.

Nose: Increased incidences of degeneration, fibrosis, hyperplasia, and squamous metaplasia occurred in 0.5 and 1.0 ppm males and females. Degeneration was also observed in 0.12 ppm females, and increased incidences of inflammation occurred in all exposed groups of males and females (Table 18). The degeneration (hyaline) was characterized by brightly eosinophilic globules of varying sizes in the cytoplasm of epithelial cells lining the nasal passage. This eosinophilic material often filled and distorted the cells. Fibrosis was characterized by increased numbers of fibroblasts and collagen in the mucosa. Hyperplastic epithelium often involved the transitional epithelium along the lateral wall with an increase in the number of cell layers. Patchy areas were observed where the cuboidal epithelium was replaced by squamous epithelium.

Larynx: Increased incidences of hyperplasia occurred in the epiglottis of six males and seven females exposed to 1.0 ppm ozone (Table 18). The hyperplasia consisted of increased numbers of cell layers; the cells tended to be cuboidal with enlarged nuclei.

Liver: There was a decreased incidence of hepatocellular adenoma or carcinoma (combined) in exposed groups of females (0 ppm, 27/50; 0.12 ppm, 22/50; 0.5 ppm, 20/50; 1 ppm, 11/50; Table D3). This decrease did not occur in males in the 2-year study or in male or female mice in the lifetime study (Tables C3, H3, and I3).

** P≤0.01
(T) Terminal sacrifice
[a] Number of animals with organ examined microscopically
[b] Number of animals with lesion
[c] Average severity grade of lesions in affected animals (1=minimal; 2=mild; 3=moderate; 4=marked).
[d] Number of animals with neoplasm per number of animals necropsied
[e] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[f] Observed incidence at terminal sacrifice
[g] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The logistic regression tests regard these lesions as nonfatal. A lower incidence in an exposure group is indicated by N.
[h] Historical incidence for 2-year inhalation studies with untreated control groups (mean ± standard deviation): 150/673 (22.3% ± 9.0); range, 10%-42%
[i] Historical incidence: 58/659 (8.8 ± 3.5); range, 0%-15%

LIFETIME STUDY

Survival

Estimates of survival probabilities for male and female mice exposed to ozone by inhalation for 130 weeks are presented in Table 19 and in Kaplan-Meier survival curves (Figure 9). Survival rates of exposed mice were similar to those of the controls.

Body Weights and Clinical Findings

The mean body weights of 1.0 ppm mice, particularly those of 1.0 ppm females, were lower than those of the controls throughout most of the study (Tables 20 and 21 and Figure 10). Due to a laboratory error, feeders for control females were not replaced on the day prior to the week 113 weighing; this resulted in a marked weight loss for control females at week 113. However, the final mean body weights of all exposed groups were similar to those of the controls.

Hypoactivity was observed in male and female mice exposed to ozone. Mice, particularly those exposed to 1.0 ppm ozone, were less active during and immediately after exposure.

TABLE 19
Survival of Mice in the Lifetime Inhalation Study of Ozone

	0 ppm	0.5 ppm	1.0 ppm
Male			
Animals initially in study	50	50	50

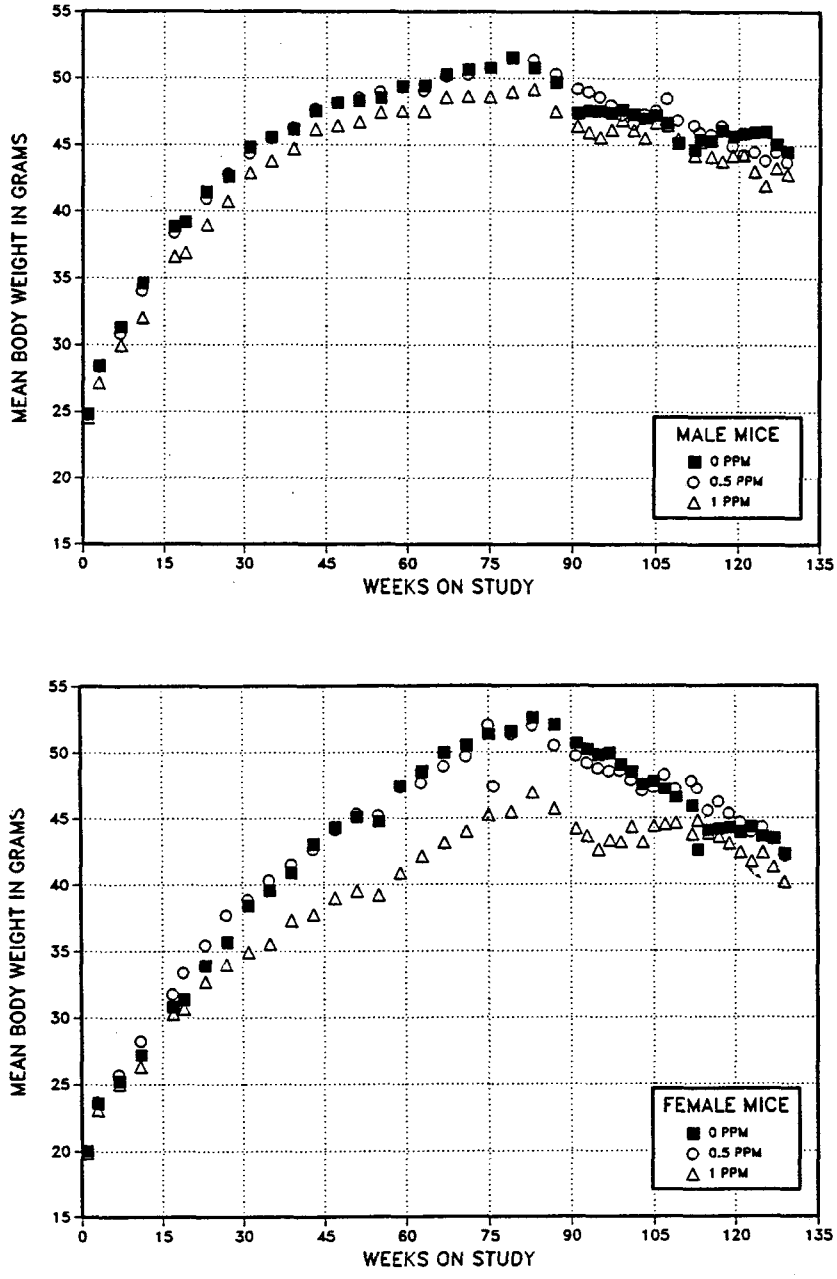

FIGURE 10
Growth Curves for Male and Female Mice Exposed to Ozone by Inhalation for 130 Weeks

Pathology and Statistical Evaluation

This section describes the statistically significant or biologically noteworthy changes in the incidences of neoplasms and nonneoplastic lesions in the lung, nose, and larynx. Summaries of the incidences of neoplasms and nonneoplastic lesions, individual animal respiratory system tumor diagnoses, and statistical analyses of primary neoplasms that occurred with an incidence of at least 5% in at least one animal group are presented in Appendix H for male mice and Appendix I for female mice.

Lung: Increased incidences of alveolar/bronchiolar adenoma or carcinoma (combined) occurred in exposed groups of males and females (Table 22). Although the increases were not statistically significant, the incidences increased with increasing ozone exposure. The incidence of carcinoma in exposed males was significantly greater than that in the controls. The incidence of adenoma in 1.0 ppm females was significantly greater than that in the controls. Multiple carcinomas occurred in male mice (0 ppm, 2/49; 0.5 ppm, 5/49; 1.0 ppm, 4/50; Table H1), and six high-dose males had both adenoma and carcinoma. When incidences of alveolar/bronchiolar adenoma or carcinoma (combined) from the 2-year and lifetime studies are considered together, the significance of the combined alveolar/bronchiolar adenoma or carcinoma incidences increases (Table 23). The use of historical controls from the NTP 2-year historical database is not applicable for these lifetime studies.

Metaplasia of the cuboidal (ciliated and nonciliated) epithelium was observed in the alveolar ducts with a minimal histiocytic infiltrate (Table 22). There were decreased incidences of hyperplasia in males and the incidences in females were similar to that of the controls.

Nose: Increased incidences of fibrosis, hyperplasia, and degeneration occurred in groups of males and females exposed to 0.5 or 1.0 ppm ozone, and an increased incidence of squamous metaplasia occurred in 1.0 ppm males and females (Table 22). The hyaline degeneration was characterized by brightly eosinophilic globules of varying size in the cytoplasm of epithelial cells lining the nasal passage and was similar to that observed in the 2-year study. Fibrosis was characterized by increased numbers of fibroblasts and collagen in the mucosa and was predominantly found in 1.0 ppm mice. The hyperplasia of the transitional epithelium along the lateral wall was similar to that seen in the 2-year study, as was the squamous metaplasia observed in 1.0 ppm mice.

Larynx: Squamous metaplasia of the epithelium at the base of the epiglottis occurred in mice and the incidences were greatest in 1.0 ppm males and females (Table 22). The increased incidence of this lesion was considered to be related to ozone exposure. The lesion was characterized by flattened cells which replaced normal cuboidal epithelium.

GENETIC TOXICOLOGY

Concurrent dosimetry was conducted with each trial because, as shown in Table J1, identical voltage and oxygen flow parameters did not ensure identical ozone concentrations. Generation of ozone from oxygen was not 100% efficient and some residual oxygen was presumably present in the exposure jar atmospheres, but the amount could not be quantified. Therefore, statistical analyses presented in Table J1 are from comparisons with air controls only, although the data for the oxygen controls are included. Comparison of the individual dose points to the oxygen control values reduced the significance of some of the responses, but did not change a mutagenic response to a nonmutagenic response in any of the experiments (see Dillon *et al.*, 1992).

No induction of mutations was observed in experiments conducted with an oxygen flow rate of 5 L/minute with strains TA98, TA100, TA104, or TA1535, (data not shown; see Dillon *et al.*, 1992). Positive responses were obtained with strain TA102, however, in all four experiments conducted, two with oxygen flow rates of 5 L/minute and two with flow rates of 7 L/minute; the data presented in Table J1 are from the second set of experiments (Dillon *et al.*, 1992). The same voltage settings were used in all experiments. In most experiments, similar results were obtained with and without S9. The positive responses occurred at the lower voltages (100, 125, and 132 volts); higher voltages, that produced higher concentrations of ozone, resulted in increasing toxicity and decreases in the numbers of mutant colonies.

PLATE 1

PLATE 4

Alveolar/bronchiolar adenoma from a control male $B6C3F_1$ mouse (arrows). The size and morphology of pulmonary neoplasms was similar in control animals and in animals exposed to ozone. H&E; 28×

DISCUSSION AND CONCLUSIONS

Ozone is the major oxidizing component in polluted air found in many urban environments. Exposure to ozone, a highly reactive toxic molecule, causes a wide variety of effects in laboratory animals (Boorman *et al.*, 1980; Eustis *et al.*, 1981; Hatch *et al.*, 1986; USEPA, 1986; Graham and Koren, 1990; Rajini *et al.*, 1993). Ozone levels which have been found in the environment cause lung inflammation, acute changes in lung function, and alterations in pulmonary structure. Changes in pulmonary function and increased numbers of inflammatory cells in pulmonary lavage fluid are also seen in humans (Koren *et al.*, 1991). The state of California and the Health Effects Institute (a nonprofit institute supported by the U.S. Environmental Protection Agency and the automobile industry) nominated ozone to the National Toxicology Program for evaluation in long-term rodent studies because of the lack of adequate information on chronic toxicity and potential carcinogenicity.

Concentrations of ozone ranging from those found in urban environments to maximum tolerated doses were used to study the toxic effects of long-term ozone exposure and to examine the effects of ozone using concentrations similar to levels at which humans may be exposed. Because rodent pulmonary neoplasms often occurred after 2 years in the diesel exhaust studies, lifetime as well as 2-year studies were included. Finally, to determine whether ozone could promote pulmonary neoplasms, a study was included in which male rats were administered 4-(*N*-methyl-*N*-nitrosamino)-1-(3-pyridyl)-1-butanone (NNK), a known pulmonary carcinogen, in addition to ozone.

Because many short-term studies have analyzed the biological effects of ozone and because differences in sensitivity to ozone among rodent strains may exist, a 4-week study was conducted to determine if F344/N rats and B6C3F$_1$ mice could tolerate the highest ozone concentrations selected for these studies. A spectrum of lesions similar to those observed in other strains of rats and mice occurred in the 4-week studies; results from the 4-week studies also indicated that 1.0 ppm ozone, the highest concentration chosen, was not likely to affect long-term survival. Because marked pulmonary edema has been observed in rats and mice exposed to 2 ppm ozone for 4 hours (Hatch *et al.*, 1986), 1.0 ppm was considered to be the highest tolerable dose for F344/N rats and B6C3F$_1$ mice.

The mean body weights of male and female rats and male mice exposed to 1.0 ppm were generally 5% to 8% lower than those of the controls throughout the 2-year and lifetime studies; mean body weights of female mice were 10% lower than that of the controls for most of the study. The mean body weights of rats and mice exposed to 0.12 or 0.5 ppm ozone were similar to those of the controls throughout the 2-year and lifetime studies.

Exposure to ozone appeared to have little effect on survival rates of rats and mice. This would suggest the ozone toxicity was not having a marked effect even though the highest doses were close to lethal concentrations.

In the present studies, toxicity observed in the pulmonary airways was similar to that observed following short-term ozone exposures (Boorman *et al.*, 1980; Hatch *et al.*, 1989; Pinkerton *et al.*, 1992), but with some notable differences. As in previous studies, the lesions tended to predominate mostly in the centriacinar region of the lung, an area that is known to be especially sensitive to the toxic effects of ozone. Both rats and mice exposed to ozone for 2 years or longer had increased numbers of inflammatory cells in the centriacinar region and an extension of the ciliated and nonciliated (Clara) bronchial cells into the alveolar ducts. Interstitial centriacinar fibrosis of the septa was observed histopathologically in rats at the end of the 2-year study and, more prominently, at the end of the lifetime study; this lesion is not as prominent (histologically) with exposures of 3 months or less. Interstitial fibrosis was diagnosed in all rats exposed to 1.0 ppm ozone in the lifetime study and in 85% or more of the 1.0 ppm rats in the 2-year study. This fibrous change was not observed in mice. Fibrosis is generally not recognized histopathologically following short-term ozone exposures, but has been documented ultrastructurally using

morphological techniques in rats exposed to peak levels of 0.25 ppm ozone for 13 and 78 weeks (Chang *et al.*, 1992).

Adaptation is a term that has been used to refer to the decreases in inflammatory response and in cellular necrosis that occur with prolonged exposure to ozone (Schwartz *et al.*, 1976; Hotchkiss *et al.*, 1989). With continuous exposures of up to 30 months, basic centriacinar ozone-induced lesions persist, and ultrastructurally the lesions are more advanced than those that develop following shorter exposure periods (Pinkerton *et al.*, 1993). This suggests that while there is adaptation in the sense that the inflammatory response subsides, the degree of cell necrosis falls with time, and cell proliferation levels drop, there continues to be remodeling and fibrosis with continuing exposure. Thus, the effects of long-term exposures would be overestimated using short-term exposures in animal models. Similarly, assuming that animals and man can adapt to ambient ozone levels may underestimate the potential hazard of long-term ozone exposures. The current studies suggest that continuous exposure to ozone over long periods of time may be expected to have cumulative adverse effects.

For policymakers, ozone concentration-response decisions are especially problematic because levels of 0.1 to 0.5 ppm exist in the environment and toxic changes are seen in rodents at these levels. In addition, levels of 0.1 to 0.5 ppm are within an order of magnitude of the lethal dose for some species (2 to 3 ppm). Increased incidences of inflammation or extension of bronchial epithelial cells (metaplasia) into the centriacinar region were observed in mice exposed to 0.5 or 1.0 ppm ozone, but not in mice exposed to 0.12 ppm ozone. While the incidences of inflammation and metaplasia in mice exposed to 0.5 or 1.0 ppm were similar, the severities were greater in the 1.0 ppm groups. Incidences of mild metaplasia were observed in 0.12 ppm male and female rats. These results suggest that the dose-response curve for ozone is very steep. Further, because adaptation occurs during acute exposures and some remodeling and fibrosis occur during long-term exposures, the concentration/time relationships for ozone toxicity are very complex.

The ozone dose-response relationship is less clear when nasal passage lesions are evaluated. In the present studies, an increase in the incidence of hyperplasia of the noncuboidal epithelium (transitional epithelium) along the lateral wall of the nasal passage occurred in rats. In addition, there was an increase in the incidence of squamous metaplasia of the epithelium in the anterior portion of the nasal passage. Increased incidences of inflammation of the nasal passage were observed in mice exposed to 0.12 ppm, suggesting that even at 0.12 ppm, ozone has a toxic effect on the epithelium lining the nasal passage. No treatment-related neoplasms were observed in the nasal passages of rats or mice. This suggests that the hyperplasia occurring in the transitional epithelium of the nasal cavity after ozone exposure has little propensity to progress to neoplasia even after 30 months of exposure (Johnson *et al.*, 1990).

While the toxicity of ozone to the respiratory passages of animals and humans has been well described, the potential of this reactive compound to affect the carcinogenic process is less clear. Ozone is mutagenic in *Salmonella typhimurium* (Dillon *et al.*, 1992) and has been reported to be carcinogenic in mice (Hassett *et al.*, 1985; Last *et al.*, 1987) but not in other species studied. The present studies suggest that ozone is not carcinogenic in the F344/N rat. Pulmonary neoplasms are less common in female rats than in male rats. In the 2-year study, two alveolar/bronchiolar carcinomas were observed in female rats exposed to 0.5 ppm ozone while no alveolar/bronchiolar carcinomas were observed in the control, 0.12, or 1.0 ppm groups. One alveolar/bronchiolar adenoma and one alveolar/bronchiolar carcinoma were observed in 2-year control males, and two alveolar/bronchiolar adenomas were observed in lifetime control males. No male exposure group had more than four alveolar/bronchiolar adenomas or carcinomas (combined). While three alveolar/bronchiolar adenomas and one alveolar/bronchiolar carcinoma were observed in 1.0 ppm male rats from the 2-year study, no alveolar/bronchiolar adenomas or carcinomas were observed in 1.0 ppm males from the lifetime study. This lack of consistency argues against even a marginal effect of ozone on the incidence of pulmonary neoplasms in the F344/N rat. Another study in rats showed that ozone exposure alone had no effect on pulmonary neoplasms (Ichinose and Sagai, 1992).

Ozone did not enhance the carcinogenic effect of NNK (a tobacco-specific nitrosamine) in rats. Rats exposed to 0.1 mg NNK/kg body weight and 0.5 ppm

ozone had three alveolar/bronchiolar adenomas; two alveolar/bronchiolar adenomas were observed in rats exposed to 0.1 mg/kg NNK without ozone. Alveolar/bronchiolar adenomas were observed in 23 rats exposed to 1.0 mg/kg NNK and 0.5 ppm ozone; 20 rats exposed to 1.0 mg/kg NNK and 0 ppm ozone had alveolar/bronchiolar adenomas. The incidence of pulmonary carcinomas was also similar between NNK/ozone rats and rats exposed only to NNK. Eleven alveolar/bronchiolar carcinomas were observed in rats exposed to 1.0 mg/kg NNK and 0.5 ppm ozone, and eight alveolar/bronchiolar carcinomas were observed in rats exposed to 1.0 mg/kg NNK alone. It is not known whether different results would have been obtained with a different carcinogenic initiator. Ichinose and Sagai (1992) have suggested that *N*-bis(2-hydroxypropyl) nitrosamine (BHPN) pulmonary tumorigenesis can be enhanced by ozone exposure, but the enhancement only occurred when ozone was administered in combination with nitrogen dioxide.

Previous studies have suggested that ozone exposure can enhance the carcinogenic process in mice (Hassett *et al.*, 1985). In the present studies, mice were administered up to 1.0 ppm ozone for 2 years or 130 weeks. There was a tendency toward increased incidences of pulmonary neoplasms with increasing ozone concentrations, but some inconsistencies were observed. In the 2-year study, a more dramatic effect was observed in female mice, primarily due to increased incidences of alveolar/bronchiolar carcinomas; two carcinomas were observed in controls and eight were observed in 1.0 ppm females. In males, there was a slight increase in the number of adenomas and the total number of neoplasm-bearing animals. A significant positive trend in the incidence of alveolar/bronchiolar adenoma or carcinoma (combined) was also observed in males in the 2-year study (0 ppm, 14/50; 0.12 ppm, 13/50; 0.5 ppm, 18/50; 1.0 ppm, 19/50). In the lifetime study, a statistically significant increased incidence of alveolar/bronchiolar carcinomas occurred in 1.0 ppm males (0 ppm, 8/49; 0.5 ppm, 15/49; 1.0 ppm 18/50). There was no increased incidence of alveolar/bronchiolar carcinomas in female mice in the lifetime study, but an increased incidence of alveolar/bronchiolar adenomas did occur in 1.0 ppm females (3/50, 3/49, 11/50). When the incidences of pulmonary neoplasms in the 2-year and lifetime studies were combined the results were more significant. There was also some suggestion for increased multiplicity of neoplasms in male mice. It appears that the concordance between studies and between sexes in a tissue where ozone would be expected to have an effect is consistent with ozone-induced pulmonary neoplasia in mice. In contrast, there was little or no evidence that increasing exposure was associated with an increased incidence of neoplasia in rats.

Because pulmonary neoplasms in mice form a spectrum of lesions and adenomas appear to progress into carcinomas with time, it is useful to examine the total number of neoplasm-bearing mice. Using the parameter of the total number of neoplasm-bearing mice, results of the present studies appear to have greater consistency; in both studies, the number of 1.0 ppm females with alveolar/bronchiolar adenoma or carcinoma (combined) was approximately twice the number of control females observed to have the neoplasm (2-year study: 0 ppm, 6/50, and 1.0 ppm, 16/50; lifetime study: 6/50 and 12/50). The males also showed an increase, though less striking, in the incidences of alveolar/bronchiolar adenoma or carcinoma (combined) (2-year study: 14/50 and 19/50; lifetime study: 16/49 and 21/50). Thus, there appears to be a consistent increase in the incidence of pulmonary neoplasms in mice with increasing ozone exposure, and it is more pronounced in females than in males.

In two studies with A/J mice, a strain that is highly susceptible to lung neoplasms, ozone exposure appeared to increase the incidence of pulmonary neoplasms (Hassett *et al.*, 1985; Last *et al.*, 1987). However, Last *et al.* (1987) found no increase in the incidence of pulmonary neoplasms in the Swiss Webster mouse. In each of these mouse strains, ozone exposure resulted in a decrease in the incidence of urethane-induced pulmonary neoplasms.

These studies support the observation that ozone increases the incidence of pulmonary neoplasms in a species (mouse) that is quite susceptible to pulmonary neoplasms. In these 2-year and lifetime NTP rat studies 1.0 ppm ozone had no effect on survival or on the incidence of pulmonary neoplasms, and further studies in rats could be predicted to be negative. The 13-month study with Wistar rats appears to confirm the lack of effect of ozone on pulmonary neoplasm incidence in rats (Ichinose and Sagai, 1992). Further study will be necessary to determine which is the most appropriate animal model for humans.

The toxic pulmonary lesion, metaplasia, occurred in both rats and mice. The continued inflammatory process and the increasing fibrosis suggests that these chronic toxic lesions may be important.

CONCLUSIONS

Under the conditions of these 2-year and lifetime inhalation studies, there was *no evidence of carcinogenic activity** of ozone in male or female F344/N rats exposed to 0.12, 0.5, or 1.0 ppm. There was *equivocal evidence of carcinogenic activity* of ozone in male $B6C3F_1$ mice based on increased incidences of alveolar/bronchiolar adenoma or carcinoma. There was *some evidence of carcinogenic activity* of ozone in female $B6C3F_1$ mice based on increased incidences of alveolar/bronchiolar adenoma or carcinoma.

There was no evidence that exposure to 0.5 ppm ozone enhanced the incidence of NNK-induced pulmonary neoplasms in male rats.

Exposure of male and female rats to ozone for 2 years or 125 weeks was associated with goblet cell hyperplasia and squamous metaplasia in the nose, squamous metaplasia in the larynx, and metaplasia (extension of bronchial epithelium into the centriacinar alveolar ducts) and interstitial fibrosis in the lung. Exposure of male and female mice to ozone for 2 years or 130 weeks was associated with hyperplasia and squamous metaplasia in the nose and inflammation (histiocytic infiltration) and metaplasia (extension of bronchial epithelium into the centriacinar alveolar ducts) of the lung.

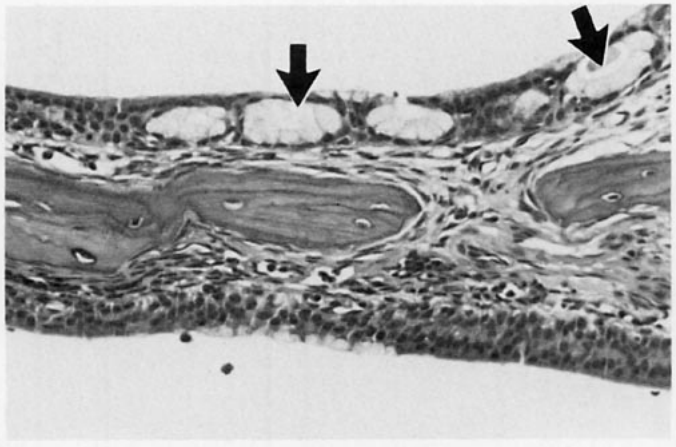

PLATE 1
Clusters of goblet cells (arrows) within the respiratory epithelium of the nasoturbinates in a male F344/N rat exposed to 1.0 ppm ozone for 2 years. H&E; 280×

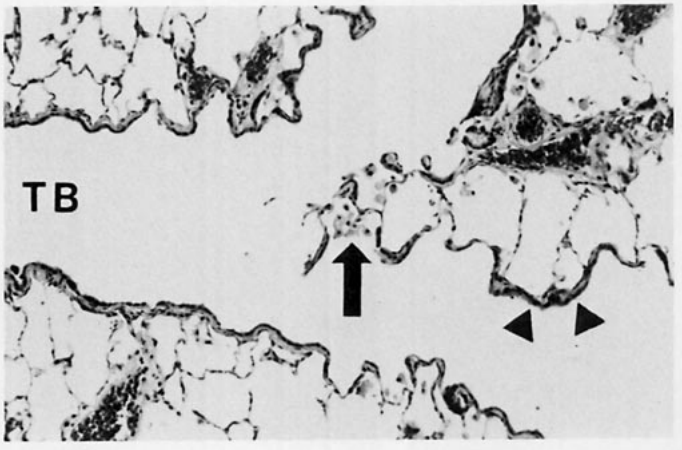

PLATE 2
Centriacinar region of the lung from a female F344/N rat exposed to 1.0 ppm ozone for 2 years. There is a cluster of macrophages (arrow) at the bifurcation of the terminal bronchiole (TB) and also thickening of the epithelium in the alveolar duct (arrowheads). H&E; 120×

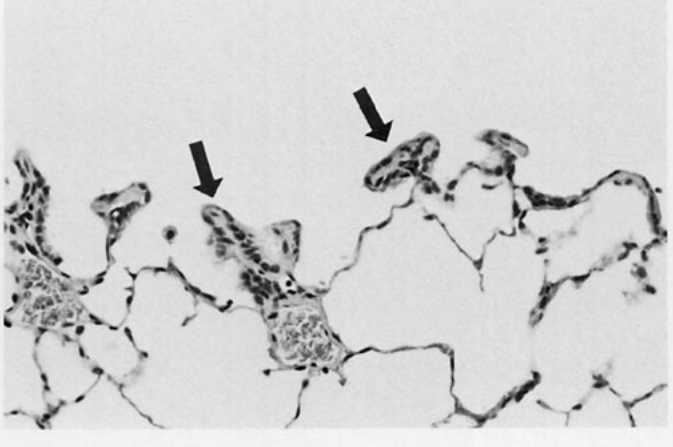

PLATE 3
Cuboidal cells (arrows) occurring between alveoli in the alveolar duct of a female F344/N rat exposed to 1.0 ppm ozone for 2 years. H&E; 210×

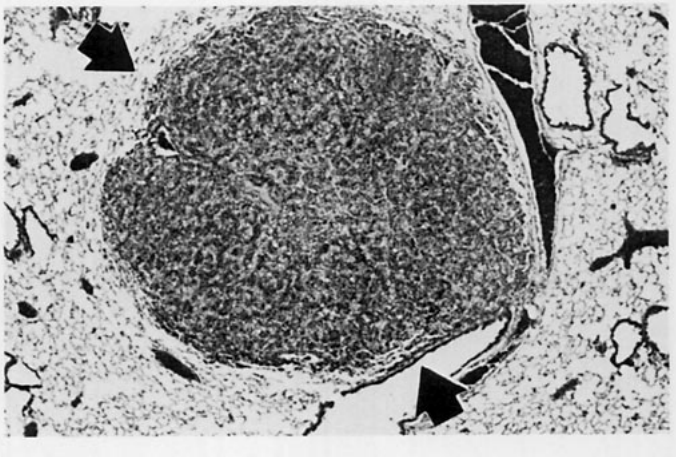

PLATE 4
Alveolar/bronchiolar adenoma from a control male B6C3F$_1$ mouse (arrows). The size and morphology of pulmonary neoplasms was similar in control animals and in animals exposed to ozone. H&E; 28×

APPENDIX A
SUMMARY OF LESIONS IN MALE RATS IN THE 2-YEAR INHALATION STUDY OF OZONE

TABLE A1	Summary of the Incidence of Neoplasms in Male Rats in the 2-Year Inhalation Study of Ozone	86
TABLE A2	Individual Animal Respiratory System Tumor Pathology of Male Rats in the 2-Year Inhalation Study of Ozone	90
TABLE A3	Statistical Analysis of Primary Neoplasms in Male Rats in the 2-Year Inhalation Study of Ozone	94
TABLE A4	Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Male F344/N Rats	100
TABLE A5	Summary of the Incidence of Nonneoplastic Lesions in Male Rats in the 2-Year Inhalation Study of Ozone	101

TABLE A1
Summary of the Incidence of Neoplasms in Male Rats in the 2-Year Inhalation Study of Ozone[a]

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Disposition Summary				
Animals initially in study	50	50	50	50
Early deaths				
Accidental deaths	1			
Moribund	35	40	36	36
Natural deaths	6	5	7	7
Survivors				
Terminal sacrifice	8	5	7	7
Animals examined microscopically	50	50	50	50
Alimentary System				
Intestine large, colon	(50)	(50)	(50)	(50)
Intestine large, rectum	(50)	(50)	(50)	(49)
Intestine large, cecum	(50)	(50)	(49)	(50)
Intestine small, duodenum	(50)	(50)	(50)	(49)
Intestine small, jejunum	(50)	(50)	(48)	(49)
Intestine small, ileum	(50)	(50)	(49)	(48)
Leiomyoma			1 (2%)	
Liver	(50)	(50)	(50)	(50)
Hepatocellular carcinoma				1 (2%)
Hepatocellular adenoma	2 (4%)	1 (2%)	1 (2%)	
Histiocytic sarcoma			1 (2%)	
Mesentery	(12)	(6)	(12)	(8)
Histiocytic sarcoma			1 (8%)	
Fat, lipoma			1 (8%)	
Oral mucosa	(1)	(1)		
Pharyngeal, squamous cell papilloma	1 (100%)	1 (100%)		
Pancreas	(50)	(50)	(50)	(50)
Adenoma	1 (2%)			
Histiocytic sarcoma			1 (2%)	
Salivary glands	(49)	(50)	(50)	(50)
Stomach, forestomach	(50)	(50)	(50)	(50)
Squamous cell papilloma			1 (2%)	
Stomach, glandular	(50)	(50)	(50)	(50)
Tooth	(2)	(2)	(1)	(2)
Odontoma				1 (50%)
Cardiovascular System				
Heart	(50)	(50)	(50)	(50)
Histiocytic sarcoma			1 (2%)	
Squamous cell carcinoma, metastatic, lung	1 (2%)			
Endocrine System				
Adrenal cortex	(50)	(50)	(50)	(50)
Adenoma	1 (2%)		1 (2%)	

TABLE A1
Summary of the Incidence of Neoplasms in Male Rats in the 2-Year Inhalation Study of Ozone (continued)

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Endocrine System (continued)				
Adrenal medulla	(50)	(50)	(50)	(50)
Pheochromocytoma malignant	1 (2%)	1 (2%)	1 (2%)	1 (2%)
Pheochromocytoma complex				1 (2%)
Pheochromocytoma benign	9 (18%)	8 (16%)	16 (32%)	7 (14%)
Bilateral, pheochromocytoma benign	8 (16%)	9 (18%)	8 (16%)	9 (18%)
Islets, pancreatic	(50)	(50)	(50)	(50)
Adenoma	4 (8%)	2 (4%)	5 (10%)	5 (10%)
Adenoma, multiple				1 (2%)
Carcinoma	3 (6%)	3 (6%)	2 (4%)	2 (4%)
Parathyroid gland	(49)	(49)	(48)	(47)
Pituitary gland	(50)	(50)	(49)	(49)
Pars distalis, adenoma	41 (82%)	43 (86%)	42 (86%)	40 (82%)
Pars distalis, carcinoma		1 (2%)		
Thyroid gland	(49)	(50)	(50)	(50)
C-cell, adenoma	1 (2%)	8 (16%)	2 (4%)	1 (2%)
C-cell, carcinoma	1 (2%)	3 (6%)	2 (4%)	1 (2%)
Follicular cell, adenoma		1 (2%)	1 (2%)	1 (2%)

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for adrenal gland, kidney, lung, pancreas, pituitary gland, preputial gland, testes, and thyroid gland; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE A4
Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Male F344/N Rats[a]

Study	Incidence in Controls		
	Adenoma	Carcinoma	Adenoma or Carcinoma
Historical Incidence at Battelle Northwest			
o-Chlorobenzalmalononitrile	4/50	0/50	4/50
α-Chloroacetophenone	1/49	1/49	2/49
Epinephrine hydrochloride	4/50	1/50	5/50
Ethyl chloride	0/50	0/50	0/50
Hexachlorocyclopentadiene	5/50	0/50	5/50
Overall Historical Incidence			
Total	15/398 (3.8%)	2/398 (0.5%)	17/398 (4.3%)
Standard deviation	4.2%	0.9%	4.5%
Range	0%-10%	0%-2%	0%-10%

[a] Data as of 31 March 1993

TABLE B3	Statistical Analysis of Primary Neoplasms in Female Rats in the 2-Year Inhalation Study of Ozone	116
TABLE B4	Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Female F344/N Rats	120
TABLE B5	Summary of the Incidence of Nonneoplastic Lesions in Female Rats in the 2-Year Inhalation Study of Ozone	121

TABLE B1
Summary of the Incidence of Neoplasms in Female Rats in the 2-Year Inhalation Study of Ozone[a]

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Disposition Summary				
Animals initially in study	50	50	50	50
Early deaths				
Moribund	19	22	17	16
Natural deaths	3	4	3	7
Survivors				
Terminal sacrifice	28	24	30	27
Animals examined microscopically	50	50	50	50
Alimentary System				
Intestine large, colon	(50)	(50)	(50)	(49)
Intestine large, rectum	(43)	(48)	(45)	(48)
Intestine large, cecum	(50)	(50)	(50)	(50)
Intestine small, jejunum	(49)	(49)	(48)	(47)
Intestine small, ileum	(50)	(49)	(48)	(47)
Liver	(50)	(50)	(50)	(50)
Hepatocellular adenoma		1 (2%)		
Histiocytic sarcoma	1 (2%)		1 (2%)	1 (2%)
Mesentery	(4)	(5)	(11)	(4)
Sarcoma			1 (9%)	
Oral mucosa	(1)	(1)		
Pharyngeal, squamous cell papilloma		1 (100%)		
Pancreas	(50)	(50)	(50)	(49)
Salivary glands	(50)	(50)	(50)	(50)
Carcinoma, metastatic, thyroid gland		1 (2%)		
Stomach, forestomach	(50)	(50)	(50)	(50)
Squamous cell carcinoma				1 (2%)
Stomach, glandular	(50)	(50)	(50)	(50)
Tongue	(1)	(1)		(1)
Squamous cell papilloma	1 (100%)	1 (100%)		
Cardiovascular System				
Heart	(50)	(50)	(50)	(50)
Endocrine System				
Adrenal cortex	(50)	(50)	(50)	(50)
Adenoma		1 (2%)	2 (4%)	1 (2%)
Carcinoma	1 (2%)	1 (2%)		
Histiocytic sarcoma	1 (2%)			
Adrenal medulla	(50)	(50)	(50)	(50)
Ganglioneuroma				1 (2%)
Pheochromocytoma complex		1 (2%)		
Pheochromocytoma benign	5 (10%)	5 (10%)	5 (10%)	4 (8%)
Bilateral, pheochromocytoma benign	1 (2%)		1 (2%)	
Islets, pancreatic	(50)	(50)	(50)	(49)
Adenoma		1 (2%)		
Carcinoma	1 (2%)	1 (2%)		

TABLE B1
Summary of the Incidence of Neoplasms in Female Rats in the 2-Year Inhalation Study of Ozone (continued)

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Endocrine System (continued)				
Pituitary gland	(50)	(49)	(50)	(49)
Histiocytic sarcoma	1 (2%)			
Pars distalis, adenoma	34 (68%)	36 (73%)	38 (76%)	33 (67%)
Thyroid gland	(50)	(50)	(50)	(50)
Bilateral, C-cell, adenoma	1 (2%)			1 (2%)
C-cell, adenoma	4 (8%)	5 (10%)	5 (10%)	1 (2%)
C-cell, carcinoma		1 (2%)	2 (4%)	
Follicular cell, adenoma			1 (2%)	
Follicular cell, carcinoma	1 (2%)	1 (2%)	1 (2%)	1 (2%)
General Body System				
None				
Genital System				
Clitoral gland	(43)	(50)	(47)	(47)
Adenoma	5 (12%)	3 (6%)	7 (15%)	8 (17%)
Carcinoma		3 (6%)	3 (6%)	1 (2%)
Histiocytic sarcoma			1 (2%)	
Bilateral, adenoma			1 (2%)	
Ovary	(50)	(50)	(49)	(49)
Arrhenoblastoma malignant	1 (2%)			
Granulosa cell tumor malignant		1 (2%)	1 (2%)	
Granulosa cell tumor benign	1 (2%)			
Granulosa-theca tumor malignant		1 (2%)		
Histiocytic sarcoma	1 (2%)			
Uterus	(50)	(50)	(49)	(50)
Deciduoma benign				1 (2%)
Polyp stromal	8 (16%)	11 (22%)	7 (14%)	6 (12%)

Cochran-Armitage test	P=0.217N			
Fisher exact test		P=0.691N	P=0.691N	P=0.339N

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for adrenal gland, clitoral gland, pituitary gland, and thyroid gland; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE B4
Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Female F344/N Rats[a]

Study	Incidence in Controls		
	Adenoma	Carcinoma	Adenoma or Carcinoma
Historical Incidence at Battelle Northwest			
o-Chlorobenzalmalononitrile	2/49	0/49	2/49
α-Chloroacetophenone	1/49	0/49	1/49
Epinephrine hydrochloride	0/50	0/50	0/50
Ethyl chloride	0/50	0/50	0/50
Hexachlorocyclopentadiene	1/50	0/50	1/50
Overall Historical Incidence			
Total	4/398 (1.0%)	0/398	4/398 (1.0%)
Standard deviation	1.5%		1.5%
Range	0%-4%		0%-4%

[a] Data as of 31 March 1993

TABLE B5
Summary of the Incidence of Nonneoplastic Lesions in Female Rats in the 2-Year Inhalation Study of Ozone[a]

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Disposition Summary				
Animals initially in study	50	50	50	50
Early deaths				
Moribund	19	22	17	16
Natural deaths	3	4	3	7
Survivors				
Terminal sacrifice	28	24	30	27
Animals examined microscopically	50	50	50	50
Alimentary System				
Intestine large, colon	(50)	(50)	(50)	(49)
Cyst				1 (2%)
Parasite metazoan	2 (4%)	2 (4%)	3 (6%)	5 (10%)
Intestine large, rectum	(43)	(48)	(45)	(48)
Parasite metazoan	4 (9%)	4 (8%)	3 (7%)	1 (2%)
Intestine large, cecum	(50)	(50)	(50)	(50)

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for liver and lung; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE C4
Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Male B6C3F$_1$ Mice[a]

Study	Incidence in Controls		
	Adenoma	Carcinoma	Adenoma or Carcinoma
Historical Incidence at Battelle Northwest			
1,3-Butadiene	18/50	5/50	21/50
Allyl glycidyl ether	7/50	0/50	7/50
α-Chloroacetophenone	7/50	6/50	11/50
Epinephrine hydrochloride	11/50	5/50	15/50
Ethyl chloride	3/50	2/50	5/50
Hexachlorocyclopentadiene	11/49	0/49	11/49
o-Chlorobenzalmalononitrile	7/49	7/49	14/49
Overall Historical Incidence			
Total	113/673 (16.8%)	45/673 (6.7%)	150/673 (22.3%)
Standard deviation	7.6%	5.6%	9.0%
Range	6%-36%	0%-16%	10%-42%

[a] Data as of 31 March 1993

TABLE C5
Summary of the Incidence of Nonneoplastic Lesions in Male Mice in the 2-Year Inhalation Study of Ozone[a]

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Disposition Summary				
Animals initially in study	50	50	50	50
Early deaths				
Moribund	16	10	19	20
Natural deaths	4	6	6	3
Survivors				
Died last week of study	1			
Terminal sacrifice	29	34	25	27
Animals examined microscopically	50	50	50	50
Alimentary System				
Gallbladder	(46)	(46)	(48)	(48)
Degeneration, hyaline		1 (2%)		
Intestine small, duodenum	(49)	(47)	(48)	(48)
Necrosis			1 (2%)	
Intestine small, ileum	(49)	(48)	(49)	(50)
Inflammation, chronic active		1 (2%)		
Peyer's patch, infiltration cellular, plasma cell	1 (2%)			
Liver	(50)	(50)	(50)	(50)
Angiectasis				1 (2%)
Basophilic focus		2 (4%)		
Clear cell focus	4 (8%)	4 (8%)	2 (4%)	1 (2%)
Cyst	1 (2%)			
Degeneration, fatty			1 (2%)	
Eosinophilic focus	1 (2%)	2 (4%)		2 (4%)
Fibrosis	1 (2%)		1 (2%)	
Hematopoietic cell proliferation			1 (2%)	
Inflammation, chronic active		1 (2%)		
Karyomegaly		1 (2%)		
Mineralization		1 (2%)		
Necrosis	3 (6%)	1 (2%)	1 (2%)	
Centrilobular, necrosis		1 (2%)		2 (4%)
Mesentery	(4)	(5)	(1)	(3)
Inflammation, chronic active		1 (20%)		
Fat, necrosis	3 (75%)	3 (60%)		3 (100%)
Pancreas	(49)	(50)	(50)	(50)
Atrophy	1 (2%)	1 (2%)		
Basophilic focus		1 (2%)		
Stomach, forestomach	(50)	(50)	(50)	(50)
Angiectasis		1 (2%)		
Hyperplasia, squamous	1 (2%)	1 (2%)		
Inflammation, acute	3 (6%)	1 (2%)		
Necrosis	1 (2%)		1 (2%)	
Stomach, glandular	(50)	(49)	(50)	(50)
Inflammation, acute			1 (2%)	
Tooth	(1)	(1)	(1)	(1)
Developmental malformation				1 (100%)
Inflammation, chronic active	1 (100%)			

[a] Number of animals examined microscopically at the site and the number of animals with lesion

TABLE C5
Summary of the Incidence of Nonneoplastic Lesions in Male Mice in the 2-Year Inhalation Study of Ozone (continued)

	0 ppm	0.12 ppm	0.5 ppm	1.0 ppm
Cardiovascular System				
Heart	(50)	(50)	(50)	(50)
Cardiomyopathy	8 (16%)	18 (36%)	11 (22%)	17 (34%)
Inflammation, chronic active	1 (2%)			
Thrombosis	1 (2%)			
Endocrine System				
Adrenal cortex	(50)	(50)	(50)	(50)
Atrophy			1 (2%)	
Hyperplasia	14 (28%)	9 (18%)	12 (24%)	15 (30%)
Hypertrophy	26 (52%)	31 (62%)	22 (44%)	22 (44%)
Capsule, hyperplasia	3 (6%)		1 (2%)	1 (2%)
Adrenal medulla	(50)	(50)	(50)	(50)
Hyperplasia	2 (4%)	2 (4%)	2 (4%)	3 (6%)
Pituitary gland	(47)	(49)	(49)	(48)
Cyst	1 (2%)		1 (2%)	1 (2%)
Pars distalis, hyperplasia	5 (11%)	2 (4%)	1 (2%)	
Thyroid gland	(49)	(50)	(50)	(50)
Inflammation, chronic				2 (4%)
Follicular cell, hyperplasia	6 (12%)	8 (16%)	10 (20%)	17 (34%)
General Body System				
None				
Genital System				
Epididymis	(50)	(50)	(50)	(50)
Granuloma sperm	1 (2%)	2 (4%)	1 (2%)	
Penis			(2)	(1)
Inflammation, acute			1 (50%)	1 (100%)
Preputial gland	(50)	(50)	(50)	(50)
Cyst			1 (2%)	
Hyperplasia	1 (2%)			
Inflammation, chronic active	12 (24%)	4 (8%)	6 (12%)	2 (4%)
Necrosis				1 (2%)
Prostate	(49)	(50)	(47)	(49)
Inflammation, suppurative	1 (2%)		2 (4%)	2 (4%)
Artery, inflammation, chronic active	1 (2%)			
Seminal vesicle	(50)	(50)	(50)	(50)
Inflammation, chronic active	1 (2%)	1 (2%)		1 (2%)
Testes	(50)	(50)	(50)	(50)
Atrophy	4 (8%)	2 (4%)	1 (2%)	4 (8%)
Mineralization	1 (2%)			3 (6%)
Interstitial cell, hyperplasia			1 (2%)	
Hematopoietic System				
Bone marrow	(49)	(50)	(50)	(50)
Atrophy	1 (2%)			
Necrosis	1 (2%)

Cochran-Armitage test	P=0.030N			
Fisher exact test		P=0.243N	P=0.100N	P=0.036N

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for adrenal gland, bone marrow, liver, lung, pituitary gland, spleen, and thyroid gland; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE D4
Historical Incidence of Alveolar/bronchiolar Neoplasms in Untreated Female B6C3F$_1$ Mice[a]

Study	Incidence in Controls		
	Adenoma	Carcinoma	Adenoma or Carcinoma
Historical Incidence at Battelle Northwest			
1,3-Butadiene	4/50	0/50	4/50
Allyl glycidyl ether	0/50	0/50	0/50
α-Chloroacetophenone	4/50	3/50	6/50
Epinephrine hydrochloride	3/50	2/50	5/50
Ethyl chloride	2/49	3/49	5/49
Hexachlorocyclopentadiene	4/48	3/48	7/48
o-Chlorobenzalmalononitrile	4/50	1/50	5/50
Overall Historical Incidence			
Total	40/659 (6.1%)	19/659 (2.9%)	58/659 (8.8%)
Standard deviation	2.8%	2.5%	3.5%
Range	0%-10%	0%-6%	0%-15%

[a] Data as of 31 March 1993

Life table test		P=0.061	P=0.228
Logistic regression test		-	P=0.500
Fisher exact test		P=1.000	P=0.500

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for lung; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Fisher exact test compares directly the overall incidence rates.
[e] Not applicable; no neoplasms in animal group
[f] Value of statistic cannot be computed.

TABLE E4
Summary of the Incidence of Nonneoplastic Lesions in Male Rats in the 2-Year Inhalation Study of Ozone/NNK[a]

	Vehicle Control	Vehicle Control/ 0.5 ppm Ozone	0.1 mg/kg NNK/ 0 ppm Ozone	0.1 mg/kg NNK/ 0.5 ppm Ozone	1.0 mg/kg NNK/ 0 ppm Ozone	1.0 mg/kg NNK/ 0.5 ppm Ozone
Disposition Summary						
Animals initially in study	48	48	48	48	48	48
Early deaths						
Moribund	36	36	40	38	41	36
Natural deaths	4	9	2	4	3	7
Survivors						
Terminal sacrifice	8	3	6	6	4	5
Animals examined microscopically	48	48	48	48	48	48
Alimentary System						
Intestine large, colon	(1)	(1)			(1)	
Mineralization	1 (100%)	1 (100%)				
Lymphoid tissue, hyperplasia, lymphoid					1 (100%)	
Intestine large, rectum	(1)	(1)				
Mineralization		1 (100%)				
Intestine large, cecum			(1)	(1)	(1)	(2)
Ulcer					1 (100%)	1 (50%)
Intestine small, ileum			(1)	(1)	(1)	(1)
Hyperplasia, lymphoid					1 (100%)	
Peyer's patch, hyperplasia, lymphoid				1 (100%)		
Liver	(26)	(28)	(27)	(36)	(39)	(42)
Angiectasis		3 (11%)	1 (4%)	3 (8%)		5 (12%)
Degeneration, cystic	5 (19%)	4 (14%)	3 (11%)	8 (22%)	7 (18%)	17 (40%)
Hepatodiaphragmatic nodule	4 (15%)	1 (4%)	2 (7%)	3 (8%)	1 (3%)	5 (12%)
Hyperplasia						2 (5%)
Hyperplasia, focal	1 (4%)	1 (4%)	1 (4%)		4 (10%)	7 (17%)
Infiltration cellular, mixed cell	1 (4%)					1 (2%)
Inflammation				1 (3%)		
Necrosis	1 (4%)					
Necrosis, focal		1 (4%)			3 (8%)	3 (7%)
Vacuolization cytoplasmic	1 (4%)	4 (14%)	4 (15%)	4 (11%)	2 (5%)	2 (5%)
Vacuolization cytoplasmic, focal	1 (4%)		1 (4%)			1 (2%)
Bile duct, hyperplasia	1 (4%)	1 (4%)	2 (7%)			1 (2%)
Centrilobular, necrosis			1 (4%)			1 (2%)
Mesentery	(8)	(8)	(10)	(11)	(8)	(8)
Fat, necrosis	7 (88%)	5 (63%)	9 (90%)	7 (64%)	6 (75%)	8 (100%)
Oral mucosa		(1)	(4)			
Pharyngeal, foreign body		1 (100%)				
Pharyngeal, hyperplasia, squamous			2 (50%)			
Pancreas	(1)	(1)			(1)	
Artery, inflammation, chronic					1 (100%)	
Stomach, forestomach	(1)	(2)		(1)	(1)	(2)
Hyperplasia, squamous						2 (100%)
Inflammation, chronic active				1 (100%)		1 (50%)
Mineralization	1 (100%)	1 (50%)				
Ulcer		1 (50%)				

[a] Number of animals examined microscopically at the site and the number of animals with lesion

TABLE E4
Summary of the Incidence of Nonneoplastic Lesions in Male Rats in the 2-Year Inhalation Study of Ozone/NNK (continued)

	Vehicle Control	Vehicle Control/ 0.5 ppm Ozone	0.1 mg/kg NNK/ 0 ppm Ozone	0.1 mg/kg NNK/ 0.5 ppm Ozone	1.0 mg/kg NNK/ 0 ppm Ozone	1.0 mg/kg NNK/ 0.5 ppm Ozone
Alimentary System (continued)						
Stomach, glandular	(1)	(3)	(1)	(1)	(3)	
Inflammation, chronic active				1 (100%)		
Mineralization	1 (100%)	2 (67%)				
Necrosis		1 (33%)			1 (33%)	
Tooth				(1)		(1)
Developmental malformation				1 (100%)		1 (100%)
Cardiovascular System						
Blood vessel	(2)	(1)				
Inflammation, chronic		1 (100%)				
Mineralization		1 (100%)				
Aorta, mineralization	2 (100%)					
Heart	(1)	(1)	(1)	(2)		(2)
Cardiomyopathy		1 (100%)				
Fibrosis						1 (50%)
Mineralization	1 (100%)					
Necrosis			1 (100%)			
Atrium, thrombosis						1 (50%)
Pericardium, fibrosis				1 (50%)		
Endocrine System						
Adrenal cortex	(4)	(3)	(1)	(1)	(4)	
Angiectasis		1 (33%)				
Vacuolization cytoplasmic					1 (25%)	
Adrenal medulla	(4)				(1)	(1)
Hemorrhage	1 (25%)					
Parathyroid gland	(2)	(1)		(1)		(1)
Hyperplasia	2 (100%)	1 (100%)		1 (100%)		1 (100%)
Pituitary gland	(34)	(29)	(35)	(27)	(34)	(30)
Pars distalis, hemorrhage						1 (3%)
Pars distalis, hyperplasia	1 (3%)		1 (3%)		2 (6%)	2 (7%)
Thyroid gland	(3)	(1)	(2)		(1)	(1)
Follicular cell, hyperplasia		1 (100%)				
General Body System						
Peritoneum	(32)	(30)	(24)	(31)	(32)	(26)
Inflammation, chronic	30 (94%)	30 (100%)	24 (100%)	30 (97%)	32 (100%)	26 (100%)
Tissue NOS	(1)	(5)				(1)
Mediastinum, inflammation, chronic active, diffuse		1 (20%)				
Genital System						
Epididymis	(1)			(1)		
Granuloma sperm	1 (100%)					

TABLE E4
Summary of the Incidence of Nonneoplastic Lesions in Male Rats in the 2-Year Inhalation Study of Ozone/NNK (continued)

	Vehicle Control	Vehicle Control/ 0.5 ppm Ozone	0.1 mg/kg NNK/ 0 ppm Ozone	0.1 mg/kg NNK/ 0.5 ppm Ozone	1.0 mg/kg NNK/ 0 ppm Ozone	1.0 mg/kg NNK/ 0.5 ppm Ozone
Genital System (continued)						
Penis	(3)	(4)	(1)	(5)	(2)	
Calculus gross observation	1 (33%)					
Calculus microscopic observation only	1 (33%)		1 (100%)			
Edema						2 (100%)
Inflammation, chronic active		2 (50%)		2 (40%)		
Preputial gland	(8)	(8)	(6)	(2)	(9)	(3)
Inflammation, chronic active	6 (75%)	5 (63%)	2 (33%)	1 (50%)	7 (78%)	3 (100%)

Fisher exact test		P=0.181N	P=0.500N

TABLE F3
Statistical Analysis of Primary Neoplasms in Male Rats in the Lifetime Inhalation Study of Ozone (continued)

	0 ppm	0.5 ppm	1.0 ppm
All Organs: Malignant Neoplasms			
Overall rate	35/50 (70%)	31/50 (62%)	33/50 (66%)
Adjusted rate	100.0%	100.0%	94.7%
Terminal rate	0/0 (0%)	0/0 (0%)	0/1 (0%)
First incidence (days)	468	345	419
Life table test	P=0.062N	P=0.517	P=0.090N
Logistic regression test	P=0.323N	P=0.387N	P=0.371N
Cochran-Armitage test	P=0.376N		
Fisher exact test		P=0.263N	P=0.415N
All Organs: Benign or Malignant Neoplasms			
Overall rate	50/50 (100%)	48/50 (96%)	49/50 (98%)
Adjusted rate	100.0%	100.0%	100.0%
Terminal rate	0/0 (0%)	0/0 (0%)	1/1 (100%)
First incidence (days)	467	345	383
Life table test	P=0.048N	P=0.334	P=0.070N
Logistic regression test	P=0.623N	P=0.990N	-[f]
Cochran-Armitage test	P=0.360N		
Fisher exact test		P=0.247N	P=0.500N

[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for adrenal gland, kidney, lung, pancreas, pituitary gland, preputial gland, testes, and thyroid gland; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group
[f] Value of statistic cannot be computed.

TABLE F4
Summary of the Incidence of Nonneoplastic Lesions in Male Rats in the Lifetime Inhalation Study of Ozone[a]

	0 ppm	0.5 ppm	1.0 ppm
Disposition Summary			
Animals initially in study	50	50	50
Early deaths			
Moribund	47	43	42
Natural deaths	3	7	7
Survivors			
Terminal sacrifice			1
Animals examined microscopically	50	50	50
Alimentary System			
Intestine large, colon	(49)	(50)	(49)
Mineralization	5 (10%)		
Parasite metazoan	2 (4%)	2 (4%)	3 (6%)

TABLE G3
Statistical Analysis of Primary Neoplasms in Female Rats in the Lifetime Inhalation Study of Ozone (continued)

	0 ppm	0.5 ppm	1.0 ppm
All Organs: Benign Neoplasms			
Overall rate	47/50 (94%)	45/50 (90%)	48/50 (96%)
Adjusted rate	100.0%	100.0%	100.0%
Terminal rate	6/6 (100%)	6/6 (100%)	7/7 (100%)
First incidence (days)	406	513	467
Life table test	P=0.230N	P=0.035N	P=0.249N
Logistic regression test	P=0.525N	P=0.084N	P=0.705N
Cochran-Armitage test	P=0.421		
Fisher exact test		P=0.357N	P=0.500
All Organs: Malignant Neoplasms			
Overall rate	34/50 (68%)	31/50 (62%)	32/50 (64%)
Adjusted rate	93.1%	95.2%	96.0%
Terminal rate	4/6 (67%)	5/6 (83%)	6/7 (86%)
First incidence (days)	417	452	285
Life table test	P=0.168N	P=0.054N	P=0.187N
Logistic regression test	P=0.313N	P=0.238N	P=0.342N
Cochran-Armitage test	P=0.377N		
Fisher exact test		P=0.338N	P=0.417N
All Organs: Benign or Malignant Neoplasms			
Overall rate	49/50 (98%)	48/50 (96%)	50/50 (100%)
Adjusted rate	100.0%	100.0%	100.0%
Terminal rate	6/6 (100%)	6/6 (100%)	7/7 (100%)
First incidence (days)	406	452	285
Life table test	P=0.232N	P=0.047N	P=0.251N
Logistic regression test	P=0.605	P=0.242N	P=0.500
Cochran-Armitage test	P=0.360		
Fisher exact test		P=0.500N	P=0.500

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for adrenal gland, clitoral gland, pituitary gland, and thyroid gland; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE G4
Summary of the Incidence of Nonneoplastic Lesions in Female Rats in the Lifetime Inhalation Study of Ozone[a]

	0 ppm	0.5 ppm	1.0 ppm
Disposition Summary			
Animals initially in study	50	50	50
Early deaths			
Moribund	36	37	40
Natural death	8	7	3
Survivors			
Terminal sacrifice	6	6	7
Animals examined microscopically	50	50	50
Alimentary System			
Intestine large, colon	(49)	(50)	(50)

Cochran-Armitage test	P=0.434N		
Fisher exact test		P=0.006	P=0.500N

[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for liver, lung, and spleen; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

TABLE H4
Summary of the Incidence of Nonneoplastic Lesions in Male Mice in the Lifetime Inhalation Study of Ozone[a]

	0 ppm	0.5 ppm	1.0 ppm
Disposition Summary			
Animals initially in study	50	50	50
Early deaths			
Moribund	26	30	23
Natural deaths	10	9	15
Survivors			
Terminal sacrifice	14	11	12
Animals examined microscopically	50	50	50
Alimentary System			
Gallbladder	(43)	(44)	(40)
Inflammation, suppurative		1 (2%)	2 (5%)
Mineralization			1 (3%)
Epithelium, hyperplasia		1 (2%)	
Intestine small, duodenum	(44)	(45)	(38)
Necrosis	1 (2%)		
Intestine small, jejunum	(43)	(44)	(41)
Peyer's patch, hyperplasia			2 (5%)
Liver	(49)	(50)	(50)
Angiectasis			1 (2%)
Basophilic focus	2 (4%)	1 (2%)	2 (4%)
Clear cell focus	1 (2%)		
Degeneration, fatty	2 (4%)	1 (2%)	2 (4%)
Eosinophilic focus	10 (20%)	9 (18%)	3 (6%)
Hematopoietic cell proliferation	2 (4%)	1 (2%)	1 (2%)
Hepatodiaphragmatic nodule	1 (2%)		1 (2%)
Infiltration cellular, mast cell			1 (2%)
Inflammation, chronic	2 (4%)	1 (2%)	1 (2%)
Necrosis	3 (6%)	8 (16%)	3 (6%)

(T)Terminal sacrifice
[a] Number of neoplasm-bearing animals/number of animals examined. Denominator is number of animals examined microscopically for bone marrow, liver, lung, ovary, pituitary gland, and spleen; for other tissues, denominator is number of animals necropsied.
[b] Kaplan-Meier estimated neoplasm incidence at the end of the study after adjustment for intercurrent mortality
[c] Observed incidence at terminal kill
[d] Beneath the control incidence are the P values associated with the trend test. Beneath the exposed group incidence are the P values corresponding to pairwise comparisons between the controls and that exposed group. The life table test regards neoplasms in animals dying prior to terminal kill as being (directly or indirectly) the cause of death. The logistic regression test regards these lesions as nonfatal. The Cochran-Armitage and Fisher exact tests compare directly the overall incidence rates. For all tests, a negative trend or a lower incidence in an exposure group is indicated by N.
[e] Not applicable; no neoplasms in animal group

APPENDIX J
GENETIC TOXICOLOGY

SALMONELLA TYPHIMURIUM MUTAGENICITY TEST PROTOCOL 262
RESULTS 262
TABLE J1 Mutagenicity of Ozone in *Salmonella typhimurium* 263

GENETIC TOXICOLOGY

SALMONELLA TYPHIMURIUM MUTAGENICITY TEST PROTOCOL

Testing was performed as reported by McGregor *et al.* (1989) for the testing of gases, with modifications as described in Dillon *et al.* (1992). Each *Salmonella typhimurium* tester strain (TA98, TA100, TA102, TA104, or TA1535), either in buffer or S9 mix (metabolic activation enzymes and cofactors from Aroclor 1254-induced male F344/N rat liver), was added to top agar and used to overlay Vogel-Bonner plates (three plates per concentration). Plates, with lids slightly raised to facilitate ozone circulation, were stacked in glass jars equipped with tapped, ground glass lids. Ozone was produced using an Ozone Generator, Type GLX (Argentox, Hamburg, Germany), operating via an electrical discharge in dry oxygen. Different concentrations of ozone were achieved by varying the flow rate of oxygen and the voltage. To expose the cells, generator voltage was applied to the oxygen flow for 5 minutes and the jars were sealed to maintain ozone atmospheres for an additional 30 minutes. Residual ozone was purged with air after this 30 minute exposure period. Plates were incubated at 37° C for 2 days in the jars and then for 1 day outside the jars. Histidine-independent mutant colonies arising on these plates were counted with a Biotran III colony counter.

The parametric method of Dunnett (1955), involving calculation of Student's *t*-statistic, was used to determine the significance of the mean counts at each individual dose level. To analyze dose responses, a nonparametric ranking procedure was used (Wahrendorf *et al.*, 1985).

RESULTS

Concurrent dosimetry was conducted with each trial because, as shown in Table J1, identical voltage and oxygen flow parameters did not ensure identical ozone concentrations. Generation of ozone from oxygen was not 100% efficient and some residual oxygen was presumably present in the exposure jar atmospheres, but the amount could not be quantitated. Therefore, statistical analyses presented in Table 1 are from comparisons with air controls only, although the data for the oxygen controls are included. Comparison of the individual dose points to the oxygen control values reduced the significance of some of the responses, but did not change a mutagenic response to a nonmutagenic response in any of the experiments (see Dillon *et al.*, 1992).

No induction of mutations was observed in experiments conducted with an oxygen flow rate of 5 L/minute with strains TA98, TA100, TA104, or TA1535 (data not shown; see Dillon *et al.*, 1992). Positive responses were obtained with strain TA102, however, in all four experiments conducted, two with oxygen flow rates of 5 L/minute and two with flow rates of 7 L/minute; the data presented in Table 1 are from the second set of experiments (Dillon *et al.*, 1992). The same voltage settings were used in all experiments. In most experiments, similar results were obtained with and without S9. The positive responses occurred at the lower voltages (100, 125, and 132 volts); higher voltages, that produced higher concentrations of ozone, resulted in increasing toxicity and decreases in the numbers of mutant colonies.

Trial summary			Positive	Positive	Positive	Positive
Positive control[c]			752 ± 3**	512 ± 29**	1,016 ± 69**	2,307 ± 261**

** Significantly different from air controls ($P<0.01$) by Dunnett's test.
[a] The detailed protocol and these data are presented in Dillon *et al.* (1992). Flow rate of oxygen, 7 L/minute.
[b] Slight toxicity, manifested by thinning of background lawn.
[c] 2-Aminoanthracene was used in the presence of S9. In the absence of metabolic activation, mitomycin-C was tested.

CHEMICAL CHARACTERIZATION, DOSE FORMULATION STUDIES, AND GENERATION OF CHAMBER CONCENTRATIONS

PROCUREMENT AND CHARACTERIZATION

Ozone

Ultra-high purity compressed oxygen for the generation of ozone was obtained in nine lots. Lots 12636-11 and 12821-24 were manufactured by A.L. Welding Compressed Gases (Kennewick, WA). Lot 12636-11 was used throughout the 4-week studies and for part of the 2-year studies, and lot 12821-24 was used for part of the lifetime studies. Lot 12636-58 was manufactured by Alphagaz Specialty Gases, Division of Liquid Air Corporation (Denver, CO), and it was used for part of the 2-year and lifetime studies. Lots 12733-38, 12733-81, 12733-115, 12733-121, and 12733-142 were manufactured by Scott Specialty Gases (Fremont, CA), and were used for part of the 2-year and lifetime studies. Lot 12821-7 was manufactured by Linde Gases (Torrance, CA), and it was used for part of the 2-year and lifetime studies.

A certification of oxygen purity was obtained from each of the vendors, which showed that the supplied compressed oxygen purity was greater than 99.9%. The impurities were nitrogen (<40 ppm), water (<2 ppm), carbon dioxide (<2 ppm), and total hydrocarbon (1 ppm as methane). Oxygen purity was acceptable for the studies.

The cylinders of compressed oxygen were stored in the study laboratory's outdoor storage area for compressed gases at ambient temperatures. When needed, the compressed oxygen cylinders were transferred to the exposure generation room where they were fitted with pressure regulators and attached to the ozone system inlet manifold.

4-(*N*-methyl-*N*-nitrosoamino)-1-(3-pyridyl)-1-butanone

The 4-(*N*-methyl-*N*-nitrosoamino)-1-(3-pyridyl)-1-butanone (NNK) was obtained from Chemsyn Science Laboratories (Lenexa, KS) in one lot (86-034-01-06). Identity, purity, and stability analyses were conducted by Research Triangle Institute (RTI). Reports on analyses performed in support of the NNK studies are on file at the National Institute of Environmental Health Sciences (NIEHS).

The chemical, a yellow crystalline solid, was identified as NNK by infrared, ultraviolet/visible, nuclear magnetic resonance, and mass spectroscopy. All spectra were consistent with those expected for a mixture of the two NNK geometric isomers (Z and E forms) (Figures L1 and L2).

The purity was determined by Karl Fischer water analysis, thin-layer chromatography (TLC), and high performance liquid chromatography (HPLC). TLC was performed using two systems: 1) silica gel 60 F-254 plates with chloroform:methanol (90:10) as the solvent; and 2) Whatman KC18F plates with acetonitrile:0.25 M sodium chloride (60:40) as the solvent. Visualization was accomplished with ultraviolet light (254 nm) and I_2 vapors. HPLC was performed using two systems: A) reverse phase, DuPont Zorbax C8 column using ultraviolet detection (210 nm) and a solvent system of 0.005 M pentane sulfonic acid in acetonitrile:water (85:15) at a flow rate of 2 mL/minute; B) normal phase, DuPont Zorbax CN column using ultraviolet detection (275 nm) and a solvent system of hexane:isopropanol:dimethyl formamide (95:3:2) at a flow rate of 2 mL/minute.

Karl Fischer water analysis indicated 0.57% ± 0.011% water. TLC by each system indicated one spot and no impurities. HPLC revealed no impurities and separated the two geometric isomers E (88%) and Z (12%). The overall purity was determined to be greater than 99%. Subsequent purity analyses performed by the study laboratory using gas chromatography methods also found the overall purity to be greater than 99%.

Stability studies of the bulk chemical were performed by RTI. HPLC was performed using system A described for the purity analysis. These studies indicated that NNK was stable as a bulk chemical for at least 2 weeks when stored in the dark at temperatures up to at least 26° C. To ensure stability, the bulk chemical was stored in the original container under a nitrogen blanket protected from light at approximately 5° C.

Trioctanoin

The trioctanoin was obtained from Eastman Kodak Company, (Rochester, NY) in one lot, which was assigned the lot number M061289. Midwest Research Institute (MRI) identified the chemical, a light yellow transparent liquid, as trioctanion by infrared, ultraviolet/visible, and nuclear magnetic resonance spectroscopy. All spectra were consistent with the structure of trioctanoin.

Purity was determined by Karl Fischer water analysis, elemental analysis, titrations for acid values, saponification value, and ester value, thin layer chromatography (TLC), and gas chromatography. Karl Fischer water analysis indicated less than 0.1% water. TLC was performed on Silica gel 60A F-254 plates using two solvent systems: 1) cyclohexane: 1,4-dioxane (95:5); and 2) carbon tetrachloride: chloroform: methanol: glacial acetic acid (60:40:1:1). Visualization was accomplished with UV light (254nm) and with a spray of potassium dichromate in 40% sulfuric acid. Gas chromatography was performed with a flame ionization detector (FID) and a helium carrier gas. Two systems were used: A) 1% SP 1000 on 100/120 Supelcoport with an oven temperature program of 185° C initially then 185° to 250° C at 10° C/min; and B) DB-1 Megabore with an oven temperature program of 50° C initially then to 275° C at 10° C/min. No attempt was made to determine the relative amounts of the two isomers (1,2- and 1,3-trioctanoin).

Elemental analyses for carbon and hydrogen were in agreement with the theoretical values for trioctanoin. Free acid titration with 0.1 N sodium hydroxide required 8.43 mg KOH per gram of trioctanoin, equivalent to 2.17% octanoic acid in trioctanoin. Saponification titration indicated a value of 357 mg KOH per gram of sample. The ester value was calculated at 93% of the theoretical value. TLC indicated a major band and a minor and three trace impurities. Gas chromatography indicated a major peak and several impurity peaks with a cumulative area of approximately 7% relative to the major peak. The largest impurity (5.1%) was identified by a gas chromatograph/mass spectrometer as dioctanoin. The study laboratory analyzed the bulk chemical for peroxide content. All of the trioctanoin used for dose preparation was found to have a peroxide content of less than 3 mEq/kg.

Stability studies of the bulk chemical were performed by MRI. Gas chromatography was performed using system A described for the triocatoin purity analysis. These studies indicated that trioctanoin was stable as a bulk chemical for 2 weeks when stored protected from light at temperatures up to 60° C. To ensure stability, the bulk chemical was stored in containers with a nitrogen headspace at room temperature protected from light.

PREPARATION AND ANALYSIS OF DOSE FORMULATIONS

NNK/Trioctanoin

Dose formulations (NNK in trioctanoin) were prepared every 3 weeks by mixing NNK with trioctanoin (Table L1). Trioctanoin was filtered through charcoal and Celite immediately before being used for dose preparation. The dose formulations were stored at 25° C for up to 3 weeks.

Stability analysis of the 0.1 mg/kg dose formulation was performed on aqueous extracts by HPLC using system A described for the NNK purity analysis with the addition of *p*-hydroxyacetophenone as the internal standard. Stability was confirmed for 3 weeks when stored at room temperature. Periodic analyses of the dose formulations were conducted at the study laboratory using the same HPLC method. The HPLC method used by the study laboratory used a different solvent ratio (water:acetonitrile, 85:15) and a different internal standard (phenol) than the method used by RTI. Further, the HPLC solvents used by the study laboratory did not contain 0.005 M pentane sulfonic acid.

Dose formulations were analyzed at the start, middle and end of the 20-week NNK exposure period. All dose formulations used for the study were within specifications except for one 0.1 mg/mL dose formulation, which was 120% of the target formulation. One 0.1 mg/mL formulation was 80% of the target concentration, and it was discarded and remixed (Table L2). All animal room samples were within 10% of the target concentrations (Table L2).

GENERATION AND MONITORING OF CHAMBER CONCENTRATIONS

Gas Generation System: Ozone gas was generated from ≥99.9% pure oxygen using a silent arc (corona) discharge ozonator (Model O3V5-O, OREC, Phoenix, AZ)(Figure L3). The gas then passed into a distribution manifold via a main exposure on/off valve that could be operated either manually or by computer. From the manifold, it was distributed to each chamber (Model H-2000, Harford Division of Lab Products, Aberdeen, MD) (Figure L4) through pairs of metering valves and corresponding flowmeters. The ozone was delivered to each exposure chamber through these flowmeters via three-way solenoid valves located at the chamber end of the gas delivery line. This three-way valve, controlled either manually or by computer, turned the ozone to a particular chamber on or off. When the valve to a chamber was off, the ozone to that chamber was routed to the exposure system exhaust. During the exposure period, ozone was injected into the chamber inlet duct where it was diluted with conditioned chamber air to achieve the desired exposure concentrations. A diagram of the exposure suite is shown in Figure L5.

The concentration in each chamber was controlled by manually adjusting the individual chamber metering valves. The flow of ozone to each chamber was increased above its normal operating level during the startup phase by manually adjusting the flowmetering control valves. This measure was necessary due to the reactivity of the ozone with chamber surfaces, which was especially pronounced at the beginning of each exposure period.

Test Article Concentration Monitoring: Chamber concentrations were monitored using an ultraviolet spectrophotometric analyzer (Dasibi Model 1003-AH or Dasibi Model 1003-PC systems) (Glendale, CA). Initially, the UV spectrophotometric analyzer (Dasibi Model 1003-AH) was used to monitor the ozone concentration in the exposure chambers, control chamber, room, generator cabinet, and an on-line ozone standard. After approximately 14 months (2-year ozone study), or 16 months (2-year ozone/NNK study and lifetime studies) the Model 1003-AH ozone monitors were replaced with Dasibi Model 1003-PC ozone monitors/generators. This change reduced maintenance and repair costs and maintained an effective system for monitoring ozone.

For both monitoring systems, air sampled at each location was transported to the monitor by transfer lines of Teflon® tubing. Samples were directed to the ozone monitor through a set of eight computer-controlled, multiplexed Teflon valves. A sampling rate of 4 minutes per port assured that all ports were sampled approximately twice per hour.

Output of each ozone monitor (1003-AH or 1003-PC) was automatically read and recorded by the Automated Data Acquisition and Control System. Data were sent from the ozone monitors to a Hewlett-Packard (HP) 85B computer located in the exposure control room. The HP-85B computer remotely controlled the selection of the correct sample stream and the operation of each monitor. The equation for each monitor's calibration curve was contained in the HP-85B and was applied to the analog output data (voltages) transmitted by the on-line ozone monitors. The HP-85B also accumulated and printed the sample values until all positions in the eight-valve system in each room had been measured. These measurements were then sent to the executive computer for printing and storage. Each monitor was interfaced to a Dasibi Model 1003-PC ozone standard generator to assess instrument calibration drift. These standard generators also supplied an addition ozone concentration for calibration of the on-line monitors.

Each on-line monitor was calibrated by correlating the analog output of the on-line monitor with concentrations obtained using an independently calibrated, portable ozone monitor (Dasibi Model 1003-AH). Points on the calibration curve were chamber ozone reading from the portable monitor and the corresponding voltage reading obtained simultaneously from the on-line monitor. An additional calibration point was obtained by measuring the ozone output from the on-line standard generator (0.25 or 0.5 ppm).

Calibration of the portable monitor was accomplished in a fashion similar to that described above. The portable monitor was used to monitor the output from the off-line ozone standard generator (Dasibi Model 1003-PC). The output of this generator could be maintained at any desired ozone concentration in the range of 0 to 1 ppm. Points on the calibration curve for the portable monitor consisted of ozone concentration readings obtained from the standard generator and the digital readout of the portable monitor. This generator in turn was calibrated using the chemical-specific method described below.

The chemical-specific method for ozone is an adaptation of the method of Bergshoeff *et al.* (1980). Ozone was collected from the output manifold of the standard generator using a bubbler containing a pH-buffered solution of potassium iodide (KI), potassium bromide (KBr) and potassium thiosulfate. The determination of the amount of ozone collected was based on the reaction between ozone (O_3) and iodide (I^-) to yield triiodide ion (I_3^-), according to the following reaction:

$$O_3 + 3I^- + 2H^+ = I_3^- + O_2 + H_2O$$

In practice, I_3^- is formed in a buffered solution (pH 7) containing an excess of KI and KBr, and a known amount of thiosulfate ($S_2O_3^{2-}$). Immediately after it is formed, the I_3^- reacts with the thiosulfate according to the following reaction:

$$I_3^- + 2S_2O_3^{2-} = 3I^- + S_4O_6^{2-}$$

After this reaction, the excess amount of added I_3^- that remained in the solution was measured at 352 nanometers with a conventional UV/vis spectrophotometer calibrated against volumetrically prepared standards of I_3^-. The molar amounts of I_3^- and $S_2O_3^{2-}$ used in this procedure were adjusted such that the μmoles of I_3^- remaining in solution (after correcting for the blank) were equal to the number of μmoles of ozone originally collected.

This method provided an accurate and precise determination of ozone concentrations in the range from 0 to 1 ppm ozone. Moreover, the calibration of the output of the off-line generator appeared to be quite constant and reproducible over extended periods of time. If the chemical-specific method described above provided accurate results, it was expected that the slope of the calibration curve between the chemical-specific assay of ozone and the readout of the monitor in the standard generator would be unity. This was indeed observed within experimental error, which shows that the results of the calibration methods described here agree with those employed by the manufacturer (Dasibi, 1981).

Concentration Buildup and Decay: The buildup of vapor concentration in the chamber at the beginning of exposure to 90% of its final stable concentration (T_{90}) and the decay of concentration at the end of exposure to 10% (T_{10}) were measured prior to the start of each study in chambers with a full complement of mature F344/N rats and B6C3F$_1$ mice. These tests were done in conjunction with the prestart tests for the 4-week, 2-year, and 30-month ozone studies. The measurements were repeated once after the start of the 4-week, 2-year, and lifetime studies. At a chamber airflow rate of 15 air changes/hour, the theoretical value for T_{90} and T_{10} is approximately 12.5 minutes. During the buildup time, continual adjustment of the ozone flow was required to compensate for the loss of ozone in the chambers. Based on the present data a T_{90} of 12 minutes was used for the 4-week studies, and a T_{90} of 30 minutes was used for the 2-year and lifetime studies. The measurements taken during the studies were comparable to the prestart measurements, except for the 2-year rat study, in which the value of T_{90} ranged from 14 to 22 minutes, while the value for T_{10} ranged from 5 to 7 minutes.

In order to determine the persistence of the chemical in the chamber following exposure, (i.e., after terminating test article delivery), the time for the concentration to decay to less than 1% of the stable concentration was measured in the 1.0 ppm chamber. Monitoring was performed approximately every 90 days during the lifetime study when animals were present. The values were approximately 14 minutes.

Concentration Uniformity: Tests with ozone in a standard H-2000 chamber with animals present and a standard fresh air flow rate of 15 air changes per hour indicated that acceptable uniformity of the test article was not achievable.

Concentration uniformity was improved by mixing the air within the chamber with enough energy that the rate of depletion of ozone was limited primarily by the ability of the animals or other surfaces to react with the chemical and was not limited by diffusion of the chemical within the chamber. This was accomplished using a recirculation device that increased the velocity of air movement so that the mass flow of ozone past the animals was significantly greater than the removal rate of the test article. Thus, the concentration in the vicinity of the animal was not significantly different from any other location in the chamber and concentration uniformity was improved.

The configuration of the recirculation device used in this study is shown in Figure L6. A portion of the air at the exhaust of the chamber was returned to the inlet of the chamber by means of Teflon-lined tubing and a variable-speed fan. Sufficient mass flow of ozone into the chamber to overcome absorption was accomplished by increasing the concentration of the test article at the inlet of the chamber as needed.

Uniformity of ozone concentration in the exposure chambers was measured once during the 4-week studies and quarterly during the 2-year and lifetime studies. The vapor concentration was measured using the on-line ozone monitor with the automatic sampling system disabled to allow continuous monitoring from a single input line. Concentration was measured only at those front and back sampling ports where cage units contained animals.

The possible variation of test chemical concentration measured from one sample port to another during the measurement procedure is termed the total port variability (TPV) and consists of both spatial and temporal variations. Two factors contribute to the TPV. The first, the between port variability (BPV), is

the factor of interest as it represents the spatial variation of test chemical distribution within the chamber. The second factor, the within port variability (WPV), represents the temporal fluctuation of the average chemical concentration within the chamber during the time the measurements were taken.

The recirculation system provided much improved uniformity. The uniformity criterion (BPV $\leq$ 5% relative standard deviation; RSD) was met in the 4-week studies. However, the criterion was not always met in the 2-year ozone, 2-year ozone/NNK, and lifetime studies. The maximum BPV determined during the study ranged from 10.1% in the 2-year ozone mouse study, to 5.7% in the lifetime mouse study. The measurements of WPV satisfied the WPV $\leq$ 5% criterion throughout all of the studies.

Summaries of the chamber concentrations in the 4-week, 2-year ozone, 2-year ozone/NNK, and the lifetime studies are presented in Tables L3, L4, L5 and L6. The monthly mean exposure concentrations for the 2-year ozone, 2-year ozone/NNK, and the lifetime studies are presented in Figures L7-L18.

APPENDIX M
INGREDIENTS, NUTRIENT COMPOSITION, AND CONTAMINANT LEVELS IN NIH-07 RAT AND MOUSE RATION

TABLE M1	Ingredients of NIH-07 Rat and Mouse Ration	300
TABLE M2	Vitamins and Minerals in NIH-07 Rat and Mouse Ration	300
TABLE M3	Nutrient Composition of NIH-07 Rat and Mouse Ration	301
TABLE M4	Contaminant Levels in NIH-07 Rat and Mouse Ration	302

TABLE M1
Ingredients of NIH-07 Rat and Mouse Ration[a]

Ingredients[b]	Percent by Weight
Ground #2 yellow shelled corn	24.50
Ground hard winter wheat	23.00
Soybean meal (49% protein)	12.00
Fish meal (60% protein)	10.00
Wheat middlings	10.00
Dried skim milk	5.00
Alfalfa meal (dehydrated, 17% protein)	4.00
Corn gluten meal (60% protein)	3.00
Soy oil	2.50
Dried brewer's yeast	2.00
Dry molasses	1.50
Dicalcium phosphate	1.25
Ground limestone	0.50
Salt	0.50
Premixes (vitamin and mineral)	0.25

[a] NCI, 1976; NIH, 1978
[b] Ingredients were ground to pass through a U.S. Standard Screen No. 16 before being mixed.

TABLE M2
Vitamins and Minerals in NIH-07 Rat and Mouse Ration[a]

	Amount	Source
Vitamins		
A	5,500,000 IU	Stabilized vitamin A palmitate or acetate
D_3	4,600,000 IU	D-activated animal sterol
K_3	2.8 g	Menadione
d-α-Tocopheryl acetate	20,000 IU	
Choline	560.0 g	Choline chloride
Folic acid	2.2 g	
Niacin	30.0 g	
d-Pantothenic acid	18.0 g	*d*-Calcium pantothenate
Riboflavin	3.4 g	
Thiamine	10.0 g	Thiamine mononitrate
B_{12}	4,000 μg	
Pyridoxine	1.7 g	Pyridoxine hydrochloride
Biotin	140.0 mg	*d*-Biotin
Minerals		
Iron	120.0 g	Iron sulfate
Manganese	60.0 g	Manganous oxide
Zinc	16.0 g	Zinc oxide
Copper	4.0 g	Copper sulfate
Iodine	1.4 g	Calcium iodate
Cobalt	0.4 g	Cobalt carbonate

[a] Per ton (2,000 lb) of finished product

TABLE M3
Nutrient Composition of NIH-07 Rat and Mouse Ration

Nutrient	Mean ± Standard Deviation	Range	Number of Samples
Protein (% by weight)	23.43 ± 0.54	22.20 – 24.30	27
Crude Fat (% by weight)	5.29 ± 0.16	5.00 – 5.60	27
Crude Fiber (% by weight)	3.51 ± 0.41	2.60 – 4.30	27
Ash (% by weight)	6.37 ± 0.18	6.11 – 6.81	27
Amino Acids (% of total diet)			
Arginine	1.287 ± 0.084	1.100 – 1.390	10
Cystine	0.306 ± 0.075	0.181 – 0.400	10
Glycine	1.160 ± 0.050	1.060 – 1.220	10
Histidine	0.580 ± 0.024	0.531 – 0.608	10
Isoleucine	0.917 ± 0.034	0.867 – 0.965	10
Leucine	1.972 ± 0.052	1.850 – 2.040	10
Lysine	1.273 ± 0.051	1.200 – 1.370	10
Methionine	0.437 ± 0.115	0.306 – 0.699	10
Phenylalanine	0.994 ± 0.125	0.665 – 1.110	10
Threonine	0.896 ± 0.055	0.824 – 0.985	10
Tryptophan	0.223 ± 0.160	0.107 – 0.671	10
Tyrosine	0.677 ± 0.105	0.564 – 0.794	10
Valine	1.089 ± 0.057	0.962 – 1.170	10
Essential Fatty Acids (% of total diet)			
Linoleic	2.389 ± 0.233	1.830 – 2.570	9
Linolenic	0.277 ± 0.036	0.210 – 0.320	9
Vitamins			
Vitamin A (IU/kg)	6,520 ± 1,510	4,180 – 11,450	27
Vitamin D (IU/kg)	4,450 ± 1,382	3,000 – 6,300	4
α-Tocopherol (ppm)	36.92 ± 9.32	22.5 – 48.9	9
Thiamine (ppm)	18.18 ± 1.52	15.0 – 21.0	27
Riboflavin (ppm)	7.92 ± 0.93	6.10 – 9.00	10
Niacin (ppm)	100.95 ± 25.92	65.0 – 150.0	9
Pantothenic Acid (ppm)	30.30 ± 3.60	23.0 – 34.6	10
Pyridoxine (ppm)	9.25 ± 2.62	5.60 – 14.0	10
Folic acid (ppm)	2.51 ± 0.64	1.80 – 3.70	10
Biotin (ppm)	0.267 ± 0.049	0.19 – 0.35	10
Vitamin B_{12} (ppb)	40.14 ± 20.04	10.6 – 65.0	10
Choline (ppm)	3,068 ± 314	2,400 – 3,430	9
Minerals			
Calcium (%)	1.17 ± 0.09	1.00 – 1.49	27
Phosphorus (%)	0.93 ± 0.04	0.85 – 1.00	27
Potassium (%)	0.887 ± 0.067	0.772 – 0.971	8
Chloride (%)	0.526 ± 0.092	0.380 – 0.635	8
Sodium (%)	0.315 ± 0.344	0.258 – 0.370	10
Magnesium (%)	0.168 ± 0.008	0.151 – 0.180	10
Sulfur (%)	0.274 ± 0.063	0.208 – 0.420	10
Iron (ppm)	356.2 ± 90.0	255.0 – 523.0	10
Manganese (ppm)	92.24 ± 5.35	81.70 – 99.40	10
Zinc (ppm)	58.14 ± 9.91	46.10 – 81.60	10
Copper (ppm)	11.50 ± 2.40	8.090 – 15.39	10
Iodine (ppm)	3.70 ± 1.14	1.52 – 5.83	10
Chromium (ppm)	1.71 ± 0.45	0.85 – 2.09	9
Cobalt (ppm)	0.797 ± 0.23	0.490 – 1.150	6

TABLE M4
Contaminant Levels in NIH-07 Rat and Mouse Ration

	Mean ± Standard Deviation[a]	Range	Number of Samples
Contaminants			
Arsenic (ppm)	0.36 ± 0.18	0.10 – 0.70	25
Cadmium (ppm)	<0.20		25
Lead (ppm)	0.30 ± 0.23	0.10 – 1.30	25
Mercury (ppm)	<0.05		25
Selenium (ppm)	0.33 ± 0.13	0.05 – 0.60	25
Aflatoxins (ppb)[b]	<5.00		25
Nitrate nitrogen (ppm)	12.24 ± 5.18	2.90 – 21.0	25
Nitrite nitrogen (ppm)	0.22 ± 0.18	<0.10 – 0.70	25
BHA (ppm)	1.81 ± 1.58	<1.00 – 10.0	25
BHT (ppm)	1.55 ± 1.53	<1.00 – 8.00	25
Aerobic plate count (CFU/g)[c]	73,867 ± 138,519	4,100 – 710,000	25
Coliform (MPN/g)[d]	3.04 ± 0.19	3.00 – 4.00	25
E. coli (MPN/g)[d]	<3.00		25
Total Nitrosoamines (ppb)[e]	7.74 ± 2.42	4.80 – 16.50	25
N-Nitrosodimethylamine (ppb)[e]	5.88 ± 1.88	3.80 – 13.00	25
N-Nitrosopyrrolidine (ppb)[e]	1.86 ± 1.05	1.00 – 4.30	25
Pesticides (ppm)			
α-BHC	<0.01		25
β-BHC	<0.02		25
γ-BHC	<0.01		25
δ-BHC	<0.01		25
Heptachlor	<0.01		25
Aldrin	<0.01		25
Heptachlor epoxide	<0.01		25
DDE	<0.01		25
DDD	<0.01		25
DDT	<0.01		25
HCB	<0.01		25
Mirex	<0.01		25
Methoxychlor	<0.05		25
Dieldrin	<0.01		25
Endrin	<0.01		25
Telodrin	<0.01		25
Chlordane	<0.05		25
Toxaphene	<0.10		25
Estimated PCBs	<0.20		25
Ronnel	<0.01		25
Ethion	<0.02		25
Trithion	<0.05		25
Diazinon	<0.10		25
Methyl parathion	<0.02		25
Ethyl parathion	<0.02		25
Malathion	0.28 ± 0.26	<0.05 – 1.00	25
Endosulfan I	<0.01		25
Endosulfan II	<0.01		25
Endosulfan sulfate	<0.03		25

[a] For values less than the limit of detection, the detection limit is given as the mean.
[b] No aflatoxin measurement was recorded for the lot milled 10-02-89.
[c] CFU = colony forming units.
[d] MPN = most probable number.
[e] All values were corrected for percent recovery.

APPENDIX N
SENTINEL ANIMAL PROGRAM

METHODS 304
TABLE N1 Murine Virus Antibody Determinations for Rats and Mice in the 4-Week, 2-Year, and Lifetime Inhalation Studies of Ozone and Ozone/NNK 307

SENTINEL ANIMAL PROGRAM

METHODS

Rodents used in the Carcinogenesis Program of the National Toxicology Program are produced in optimally clean facilities to eliminate potential pathogens that may affect study results. The Sentinel Animal Program is part of the periodic monitoring of animal health that occurs during the toxicologic evaluation of chemical compounds. Under this program, the disease state of the rodents is monitored via serology on sera from extra (sentinel) animals in the study rooms. These animals and the study animals are subject to identical environmental conditions. The sentinel animals come from the same production source and weanling groups as the animals used for the studies of chemical compounds.

Serum samples were collected from as many as 16 randomly selected rats and mice during the 4-week, 2-year, and lifetime studies. Blood from each animal was collected, allowed to clot, and the serum separated. The samples were processed appropriately and sent to Microbiological Associates, Inc. (Bethesda, MD) for determination of antibody titers. The laboratory serolgy methods and viral agents for which testing was performed are tabulated below; the times at which blood was collected during the studies are also listed.

Method and Test	Time of Analysis
RATS	
4-Week study	
ELISA	
Mycoplasma pulmonis	Study termination
PVM (pneumonia virus of mice)	Study termination
RCV/SDA (rat coronavirus/sialodacrydoadenitis virus)	Study termination
Sendai	Study termination
Hemagglutination inhibition	
H-1 (Toolan's H-1 virus)	Study termination
KRV (Kilham rat virus)	Study termination
2-Year study	
ELISA	
Mycoplasma arthritidis	24 months
M. pulmonis	24 months
PVM	6, 12, 18, and 24 months
RCV/SDA	6, 12, 18, and 24 months
Sendai	6, 12, 18, and 24 months
Immunofluorescence assay	
RCV/SDA	18 months
Hemagglutination inhibition	
H-1	6, 12, 18, and 24 months
KRV	6, 12, 18, and 24 months

Method and Test	Time of Analysis
RATS (continued)	
2-Year ozone/NNK study	
ELISA	
M. arthritidis	24 months
M. pulmonis	24 months
PVM	6, 12, 18, and 24 months
RCV/SDA	6, 12, 18, and 24 months
Sendai	6, 12, 18, and 24 months
Immunofluorescence Assay	
Sendai	24 months
Hemagglutination Inhibition	
H-1	6, 12, 18, and 24 months
KRV	6, 12, 18, and 24 months
Lifetime study	
ELISA	
M. arthritidis	30 months
M. pulmonis	30 months
PVM	6, 12, 18, and 30 months
RCV/SDA	6, 12, 18, and 30 months
Sendai	6, 12, 18, and 30 months
Immunofluorescence assay	
PVM	12 months
Hemagglutination inhibition	
H-1	6, 12, 18, and 30 months
KRV	6, 12, 18, and 30 months
MICE	
2-Year study	
ELISA	
Ectromelia virus	6, 12, 18, and 24 months
EDIM (epizootic diarrhea of infant mice)	6, 12, and 24 months
GDVII (mouse encephalomyelitis virus)	6, 12, 18, and 24 months
LCM (lymphocytic choriomeningitis virus)	6, 12, 18, and 24 months
Mouse adenoma virus	6, 1,2 18, and 24 months
MHV (mouse hepatitis virus)	6, 12, 18, and 24 months
M. arthritidis	24 months
M pulmonis	24 months
PVM	6, 12, 18, and 24 months
Reovirus 3	6, 12, 18, and 24 months
Sendai	6, 12, 18, and 24 months

Method and Test	Time of Analysis
MICE (continued)	
2-Year study (continued)	
Immunofluorescence assay	
EDIM	18, and 24 months
MVM (minute virus of mice)	6 months
Reovirus 3	6 and 12 months
Hemagglutination inhibition	
MVM	12, 18, and 24 months
K (papovavirus)	6, 12, 18, and 24 months
Polyoma virus	6, 12, 18, and 24 months
Reovirus 3	6 months
Lifetime study	
ELISA	
Ectromelia virus	6, 12, and 30 months
EDIM	6, 12, and 30 months
GDVII	6, 12, and 30 months
LCM	6, 12, and 30 months
Mouse adenoma virus	6, 12, and 30 months
MHV	6, 12, and 30 months
M. arthritidis	30 months
M. pulmonis	30 months
PVM	6, 12, and 30 months
Reovirus 3	6, 12, and 30 months
Sendai	6, 12, and 30 months
Immunofluorescence assay	
MHV	30 months
MVM	6 months
Reovirus 3	6, 12 months
Hemagglutination inhibition	
MVM	12 and 30 months
K	6, 12, and 30 months
Polyoma virus	6, 12, and 30 months
Reovirus 3	6 months

Results of serology tests are presented in Table N1.

TABLE N1
Murine Virus Antibody Determinations for Rats and Mice in the 4-Week, 2-Year, and Lifetime Inhalation Studies of Ozone and Ozone/NNK

Interval	Incidence of Antibody in Sentinel Animals	Positive Serologic Reaction for
4-Week Studies		
Rats		
Study termination	0/10	None positive
Mice		
Study termination	0/10	None positive
2-Year Studies		
Rats		
Study initiation	0/10	None positive
6 Months	0/16	None positive
12 Months	0/16	None positive
18 Months	0/12	None positive
Study termination	0/10	None positive
Mice		
Study initiation	0/10	None positive
6 Months	0/10	None positive
12 Months	0/10	None positive
18 Months	0/9	None positive
Study termination	0/10	None positive
2-Year Study Ozone/NNK		
Rats		
Study initiation	0/10	None positive
6 Months	0/10	None positive
12 Months	0/10	None positive
18 Months	0/13	None positive
Study termination	3/10[a]	*M. arthritidis*
Lifetime Studies		
Rats		
Study initiation	0/10	None positive
6 Months	0/12	None positive
12 Months	0/12	None positive
18 Months	1/11[b]	H-1 and KRV
Study termination	1/10	*M. arthritidis*
Mice		
Study initiation	0/10	None positive
6 Months	0/10	None positive
12 Months	0/10	None positive
Study termination	2/10	*M. arthritidis*

[a] Two animals positive for *M. arthritidis* were housed in the NNK/air chamber, and one animal was housed in the NNK/Ozone chamber.

[b] Further evaluation by immunofluorescence antibody assay indicated that this was a false positive response.

412	4,4-Diamino-2,2-stilbenedisulfonic Acid
413	Ethylene Glycol
414	Pentachloroanisole
415	Polysorbate 80
416	*o*-Nitroanisole
417	*p*-Nitrophenol
418	*p*-Nitroaniline
419	HC Yellow 4
420	Triamterene
421	Talc
422	Coumarin
423	Dihydrocoumarin
424	*o*-Benzyl-*p*-chlorophenol
425	Promethazine Hydrochloride
426	Corn Oil, Safflower Oil, and Tricaprylin
427	Turmeric Oleoresin
428	Manganese (II) Sulfate Monohydrate
430	C.I. Direct Blue 218
431	Benzyl Acetate
432	Barium Chloride Dihydrate
433	Tricresyl Phosphate
434	1,3-Butadiene
437	Hexachlorocyclopentadiene
443	Oxazepam
