THE EPISKIN™ TEST
(AN IN VITRO TEST FOR SKIN CORROSIVITY)

STATEMENT ON THE SCIENTIFIC VALIDITY OF
THE RAT SKIN TRANSCUTANEOUS ELECTRICAL
RESISTANCE (TER) TEST (AN IN VITRO TEST FOR SKIN CORROSIVITY)

At its 10th meeting, held on 31 March 1998 at the European Centre for the Validation of Alternative Methods (ECVAM), Ispra, Italy, the ECVAM Scientific Advisory Committee (ESAC) unanimously endorsed the following statement:

The results obtained with the rat skin transcutaneous electrical resistance (TER) test in the ECVAM International validation study on in vitro tests for skin corrosivity were reproducible, both within and between the three laboratories that performed the test. The rat skin TER test proved applicable to testing a diverse group of chemicals of different physical forms, including organic acids, organic bases, neutral organics, inorganic acids, inorganic bases, inorganic salts, electrophiles, phenols and soaps/surfactants. The concordances between the skin corrosivity classifications derived from the in vitro data and from the in vivo data were very good. The test was able to distinguish between corrosive and non-corrosive chemicals for all of the chemical types studied. The Committee therefore agrees with the conclusion from this formal validation study that the rat skin TER test is scientifically validated for use as a replacement for the animal test for distinguishing between corrosive and non-corrosive chemicals, and that this test is ready to be considered for regulatory acceptance.

The ESAC has been regularly kept informed of the progress of the study, and this endorsement was based on an assessment of various documents, including, in particular, the report on the results and evaluation of the validation study by the Management Team, which is to be published in Toxicology in Vitro. This validation study was conducted in accordance with the general principles laid down in the report of the CAAT/ERGATT workshop held in 1990, guidelines contained in the report of an ECVAM/ERGATT workshop held in 1995, criteria laid down by ECVAM and the ECB, criteria recommended at an OECD workshop held in 1996, and the US ICCVAM report on validation and regulatory acceptance. The outcome of a prevalidation study on in vitro tests for skin corrosivity was published in 1995, as ECVAM workshop report 6. A separate report on the selection of the test chemicals for the validation study is to be published alongside the Management Team’s report in Toxicology In Vitro.

    international validation study on in vitro tests for skin corrosivity. 1. Selection and distribution of the
    test chemicals. Toxicology in Vitro, in press.

General Information about the ECVAM skin corrosivity validation study:

A. The study was coordinated from ECVAM, and the Management Team (MT) was chaired by Dr Julia
   Fentem (ECVAM). The other four MT members acted as representatives of the “lead laboratories”
   and each took responsibility for one of the four tests included in the validation study: Dr Rodger
   Curren (Microbiological Associates Inc., USA; CORROSITEX®). Dr Lesley Earl (Unilever, UK; rat
   skin TER assay), Mr David Esdaile (Rhône-Poulenc Agro, France; EPISKIN™), and Dr Manfred
   Liebsch (ZEBET, Germany; Skin2™ assay). The study was principally funded by ECVAM, under the
   terms of 14 separate contracts with the participating organisations. Professor Michael Bails
   (ECVAM) and Dr Philip Botham (ESAC; ZENECA CTL, UK) represented the sponsors in any
   contacts with the MT. In addition to ECVAM, the participating organisations were: Agence du
   Medicament (France), BASF Aktiengesellschaft (Germany), BIBRA International (UK), COVANCE
   (UK), Humboldt University (Germany), Huntingdon Life Sciences (UK), INRS (France),
   Microbiological Associates Inc. (USA), Microbiological Associates Ltd (UK), Rhône-Poulenc Agro
   (France), Sanofi Recherche (France), Unilever Research (UK), ZEBET, BgVV (Germany) and
   ZENECA CTL (UK).

B. This study began in 1996, as a follow-up to a prevalidation study on in vitro tests for replacing the in
   vivo Draize rabbit test for skin corrosivity. The main objectives were to: (a) Identify tests capable of
   discriminating corrosives (C) from non-corrosives (NC) for selected groups of chemicals (e.g. organic
   acids, phenols) and/or all chemicals (single chemical entities only); and (b) determine whether the
   tests could identify correctly known R35 (UN packing group I) and R34 (UN packing groups II & III)
   chemicals. The tests selected for inclusion in the validation study were: (a) the rat skin TER assay; (b)
   CORROSITEX®; (c) the Skin2™ ZK1350 corrosivity test; and (d) EPISKIN™. Each test was
   conducted in three independent laboratories, according to the principles, criteria and procedures for
   undertaking validation studies outlined previously by ECVAM in conjunction with International
   experts in this area. Prediction models for the four tests were clearly defined in the test protocols.

C. A test set of 60 chemicals was selected by an independent Chemicals Selection Sub-Committee,
   including organic acids (6C/5NC), organic bases (7C/3NC), neutral organics (9NC), phenols
   (2C/3NC), inorganic acids (6C/1NC), inorganic bases (2C/2NC), inorganic salts (1C/2NC),
   electrophiles (3C/5NC) and soaps/surfactants (3NC). The first set of ten coded chemicals was
   distributed independently of the MT and participating laboratories in June 1996. Further to the
   satisfactory completion of the first phase of the study, the remaining 50 coded chemicals were
   distributed in September 1996. The results obtained were submitted to ECVAM's statistician, Dr
   Graeme Archer, for independent analysis in consultation with Dr Hermann-Georg Holzhütter
   (Humboldt University, Berlin, Germany). Data analysis and preparation of the final reports took place
   between May and October 1997.
D. The rat skin TER assay has been used successfully as a routine in-house test for several years. When used in screening mode, the TER method is employed to predict corrosivity potential rather than the degree of corrosive effect (i.e. potency), and it has been used primarily to guide humane in vivo skin testing. The TER assay has been evaluated in several intralaboratory and interlaboratory studies, and it performed creditably in the prevalidation study conducted during 1993 and 1994. The test protocol evaluated in this validation study had been refined on the basis of recommendations from the prevalidation study, to include a dye binding procedure for reducing the number of false positive predictions obtained previously with test materials containing surfactants and solvents. In outline, test materials are applied for up to 24 hr to the epidermal surfaces of skin discs taken from the pelts of humanely killed young rats. Corrosive materials are identified by their ability to produce a loss of normal stratum corneum integrity and barrier function, which is measured as a reduction in the inherent TER below a predetermined threshold level (5kΩ).

Rat Skin TER Assay Prediction Model:

<table>
<thead>
<tr>

| < or = 5 | 24               | > or = +ve control  | C    | R34           | II/III          |
|          | 24               | < +ve control       | NC   | no label      | -               |

aNM = not measured

E. The prediction model for the rat skin TER test was used to classify the corrosivity potentials of the 60 test chemicals on the basis of the in vitro data obtained in the three laboratories conducting the test. Comparing these in vitro classifications with the in vivo classifications independently assigned to the chemicals before the blind trial began gave the following key statistical parameters:

- Sensitivity: C 88%
  R34/II & III 18%
  R35/I 88%
- Specificity: 72%
- Predictivity: C 72%
  R34/II & III 40%
  R35/I 22%
- Accuracy: C/NC 79%
  R35/R34/NC 55%
The underprediction and overprediction rates for the TER test relative to the study objectives were:

**Objective (a): C vs NC**
- Underprediction rate: 12%
- Overprediction rate: 28%

**Objective (b): R35/I vs R34/II & III vs NC**
- Underprediction rates:
  - R35/I → NC: 6%
  - R34/II & III → NC: 14%
- Overprediction rates:
  - NC → R35/I: 12%
  - NC → R34/II & III: 16%
  - R34/II & III → R35/I: 69%

* unacceptable according to the criteria defined by the MT before undertaking the data analysis

**F.** In order for the rat skin TER test to be considered for use for legislative and other purposes, measures will be taken to press for the updating of OECD Testing Guideline 404 and Annex V method B.4 of Directive 67/548/EEC.

**G.** A statement on the scientific validity of the EPISKIN™ assay for skin corrosivity testing was also endorsed by the ESAC on 31 March 1998. The two other methods included in the validation study, CORROSITEX® and Skin2, did not meet all of the criteria for them to be considered acceptable as replacement tests. The corrosivity potentials of about 40% of the test chemicals could not be assessed with CORROSITEX®, although it may be valid for testing specific classes of chemicals (such as organic bases and inorganic acids). The Skin2 assay, as conducted in this validation study, had an unacceptably high underprediction rate (57%), although it had a specificity of 100% it is recognised that both of these methods could be useful if they were incorporated into a tiered testing strategy for skin corrosivity.

---

**STATEMENT ON THE SCIENTIFIC VALIDITY OF THE EPISKIN™ TEST**

**(AN IN VITRO TEST FOR SKIN CORROSIVITY)**

At its 10th meeting, held on 31 March 1998 at the European Centre for the Validation of Alternative Methods (ECVAM), Ispra, Italy, the ECVAM Scientific Advisory Committee (ESAC) endorsed the following statement:

The results obtained with the EPISKIN™ test (involving the use of a reconstructed human skin model) in the ECVAM international validation study on in vitro tests for skin corrosivity were reproducible, both within and between the three laboratories that performed the test. The EPISKIN test proved applicable to testing a diverse group of chemicals of different physical forms, including organic acids, organic bases, neutral organics, inorganic acids, inorganic bases, inorganic salts, electrophiles, phenols and soaps/surfactants. The concordances between the skin corrosivity classifications derived...
from the *in vitro* data and from the *in vivo* data were very good. The test was able to
distinguish between corrosive and non-corrosive chemicals for all of the chemical types
studied; it was also able to distinguish between known R35 (UN2 packing group I) and
R34 (UN packing groups II & III) chemicals. The Committee therefore agrees with the
conclusion from this formal validation study that the EPISKIN test is scientifically
validated for use as a replacement for the animal test, and that it is ready to be considered
for regulatory acceptance.

The ESAC has been regularly kept informed of the progress of the study, and this endorsement was based
on an assessment of various documents, including, in particular, the report on the results and evaluation of
the validation study by the Management Team, which is to be published in *Toxicology in vitro.*

This validation study was conducted in accordance with the general principles laid down in the report of
the CAAT/ERGATT workshop held in 1990, guidelines contained in the report of an
ECVAM/ERGATT workshop held in 1995, criteria laid down by ECVAM and the ECB, criteria
recommended at an OECD workshop held in 1996, and the US ICCVAM report on validation and
regulatory acceptance. The outcome of a prevalidation study on *in vitro* tests for skin corrosivity was

A separate report on the selection of the test chemicals for the validation study is to be published alongside the Management Team's report in
*Toxicology in vitro.*

The results obtained were submitted to ECVAM’s statistician, Dr Graeme Archer, for independent analysis in consultation with Dr Hermann-Georg Holzhütter (Humboldt University, Berlin, Germany). Data analysis and preparation of the final reports took place between May and October 1997.

D. EPISKIN™ is a three-dimensional human skin model comprising a reconstructed epidermis with a functional stratum corneum. Its use for skin corrosivity testing involves topical application of test materials to the surface of the skin for 3, 60 and 240 min, and the subsequent assessment of their effects on cell viability by using the MTT assay. An in-house evaluation and prevalidation of the test was conducted during 1994-96. On the basis of these studies, the test protocol was refined prior to its inclusion in this validation study.
