Veterinary vaccines represent an important tool for improving animal and human health by preventing a wide range of infectious diseases in animals and reducing serious zoonotic diseases in people. However, regulatory testing to meet vaccine lot release requirements can require large numbers of animals that may experience unrelieved pain and distress. NICEATM-ICCVAM organized an international workshop in partnership with ECVAM, JaCVAM and Health Canada to review the state of the science of human and veterinary vaccine potency and safety testing, and to identify priority activities to advance scientifically sound alternative methods that can further reduce, refine and replace animal use. Nearly 200 scientists from 13 countries participated in the workshop during which they identified relevant knowledge and data gaps and priority research, development and validation activities to address these gaps. This included identifying opportunities to apply new science and technology to develop improved methods. The highest priority vaccines were Rabies, *Clostridium sp.*, and *Leptospira sp.* vaccines because they require large numbers of animals and involve significant pain and distress. Vaccine challenge testing, which often requires live viruses and bacteria hazardous to laboratory workers, livestock, pets, and wildlife, were also considered high priorities. Collaborations between human and veterinary researchers working on vaccines for the same or similar organisms were recommended to leverage scientific resources and expedite progress. Implementation of the workshop recommendations will likely advance alternative methods for vaccine potency and safety testing to benefit animal welfare while ensuring continued protection of animal and human health.

**Theme:** Safety and Efficacy Testing of Chemicals: Pharmaceuticals and Biologicals

**Keywords:** vaccine; potency; safety; workshop; alternative; methods
