ICCVAM evaluated the LLNA as a stand-alone test method to determine potency categorization of chemicals that may cause allergic contact dermatitis (i.e., potential skin sensitizers). The dose per unit skin area that induces a 5% positive response rate (i.e., DSAₐ₅) in the human maximization test (HMT) or human repeat-insult patch test (HRIPT) was used as the human induction threshold. Substances with induction thresholds ≤500 µg/cm² were classified as “strong” human sensitizers. The extent to which the LLNA EC₃ (estimated concentration needed to produce a stimulation index of 3, the threshold value for a positive response) correctly categorizes strong human sensitizers was evaluated by examining 136 substances with both LLNA and human data. Using EC₃ ≤ 2%, a criterion recently adopted by the United Nations Globally Harmonized System of Classification and Labelling of Chemicals, correctly categorized 52% (14/27) of the strong human sensitizers. However, nearly half (48% [13/27]) of the strong human sensitizers had an EC₃ > 2% (11/27) or were negative in the LLNA (2/27). Of the 11 strong human sensitizers with an EC₃ > 2%, 91% (10/11) had an LLNA EC₃ value between 2% and 10%. ICCVAM concludes that the LLNA can be used to categorize substances as strong sensitizers when EC₃ ≤ 2% but cannot be used as a stand-alone assay to predict sensitization potency categories. Substances producing an LLNA EC₃ between 2% and 10% will require additional information to determine that the substance should not be categorized as a strong sensitizer. To improve the accuracy of the LLNA for identifying strong sensitizers, ICCVAM encourages the development and evaluation of integrated decision strategies that consider other types of relevant information such as quantitative structure-activity relationships, structural alerts, peptide reactivity, in vitro testing data, human data or experience, and existing data from similar chemical entities.
