

Other Outcomes

- Comment on whether the approach to search for and select human and animal studies relevant to evaluating potential long-term neurological effects of acute sarin exposure as described in the methods was objectively applied and clearly presented.
- Provide any comment on NTP's consideration of these data.
- If the human or animal data for sleep disruption, anxiety and fear, avoidance and depression, activity/strength, other neurological symptoms, electroencephalogram, or other sensory effects support a higher level of evidence conclusion (e.g., moderate or high) than what NTP proposed, please suggest the level of evidence and provide justification for that outcome.
- Identify any information that should be added or deleted.
