Subject: Cell radiation study

Comment:

I have 1 point and 1 question.

1. Question:

Is it possible that the rats that developed cancer were related?

2. Comment:

If you have a control group of 90 and 6 other groups of 90 that are tested for an effect from anything, there will be a 6 times bigger chance of occurrence of cancer in the 540 rats tested.

If whatever is tested does not cause cancer, there will be a random spread of the cancer in the 6 groups, with some groups having a higher incidence.

At least that is what my logic dictates and if I am right the study's results are even less than equivocal.
