Michler’s Ketone
CAS No. 90-94-8
Reasonably anticipated to be a human carcinogen
Also known as 4,4’-(dimethylamino)benzophenone

Carcinogenicity
Michler’s ketone is reasonably anticipated to be a human carcinogen based on sufficient evidence of carcinogenicity from studies in experimental animals.

Cancer Studies in Experimental Animals
Oral exposure to Michler’s ketone caused tumors in two rodent species and at two different tissue sites. Dietary administration of Michler’s ketone caused liver cancer (hepatocellular carcinoma) in female mice and in rats of both sexes and blood-vessel cancer (hemangiosarcoma) in male mice (NCI 1979).

Cancer Studies in Humans
No epidemiological studies were identified that evaluated the relationship between human cancer and exposure specifically to Michler’s ketone.

Properties
Michler’s ketone is a derivative of dimethylaniline and exists as white to green crystalline leaflets or blue powder at room temperature. Michler’s ketone is practically insoluble in water, very soluble in pyridimidine, soluble in alcohol and warm benzene, and very slightly soluble in ether. It is stable under normal temperatures and pressures (NCI 1979, Akron 2009, HSDB 2009). Physical and chemical properties of Michler’s ketone are listed in the following table.

Use
Michler’s ketone is a chemical intermediate used in the synthesis of at least 13 dyes and pigments, particularly auramine derivatives (NCI 1979, HSDB 2009). These pigments are used to make ultraviolet-cured printing ink for carton board and paper and as dyes for pen inks, carbon paper, alcoholic solvents, oils, waxes, textiles, and leather; one pigment is also used as a fungicide (Castle et al. 1997a,b, HSDB 2009).

Production
In 1975, U.S. production of Michler’s ketone was estimated at over 908 kg (2,000 lb) (HSDB 2009). No current production data were found. In 2009, Michler’s ketone was produced by one manufacturer in Europe (SRI 2009), and was available from 29 suppliers, including 16 U.S. suppliers (ChemSources 2009). U.S. imports of Michler’s ketone totaled 548 kg (1,206 lb) in 1972, 20,000 kg (44,000 lb) in 1975 (HSDB 2009), and about 10,900 kg (24,000 lb) in 1983 (USITC 1984). No more recent data on U.S. imports or exports were found.

Exposure
The routes of potential human exposure to Michler’s ketone are inhalation, ingestion, and dermal contact (Akron 2009). Michler’s ketone may be present in some dyes used for printing and in minute quantities in final consumer products (Ozaki et al. 2004). Michler’s ketone was measured in recycled paper and paperboard used in food packaging in Japan at concentrations of up to 12 μg/g. It was not detected in tested virgin paper or paperboard products. In another study, Michler’s ketone was not detected in food that had been in contact with packaging containing Michler’s ketone at a concentration of 3.9 μg/g (the highest concentration found in tested packaging) (Castle et al. 1997a). The U.S. Environmental Protection Agency’s Toxics Release Inventory reported environmental releases of Michler’s ketone of 1,100 lb in 1988 and 1,577 lb in 1995. In 1999, two industrial facilities released 869 lb (TRI 2009). No release data have been reported since 1999.

The potential for occupational exposure is greatest for workers in facilities that manufacture Michler’s ketone or any of the dyestuffs for which it is an intermediate (NCI 1979). The National Occupational Exposure Survey (conducted from 1981 to 1983) estimated that 2,026 workers, including 405 women, potentially were exposed to Michler’s ketone (NIOSH 1990).
